

1. What is Loose Coupling?

Tight Coupling -

Example-1:

```
public class TodoBusinessService{
    TodoDataServiceImpl dataService = new TodoDataServiceImpl();
    ...
}
```

Now here TodoBusinessService is dependent on TodoDataServiceImpl. Its directly creating a instance of TodoDataServiceImpl using new.

Example-2:

```
public class ComplexAlgorithmImpl{
    BubbleSortAlgorithm bubbleSortAlgorithm = new BubbleSortAlgorithm();
    ...
}
```

Same way ComplexAlgorithmImpl is dependent on BubbleSortAlgorithm. This is tight coupling. Suppose tommorrow we need to switch from bubble sort to quick sort, we will have to make this change in here.

Loose Coupling -

Example-1:

```
@Component
public class TodoBusinessService{

    @Autowired
    TodoDataService dataService;          // = new TodoDataService

    public TodoBusinessService(TodoDataService dataService){
        this.dataService = dataService;
    }

    .....

    public interface TodoDataService{
        List<String> retrieveTodos(String user);
    }
}
```

Now here to make it loose coupling, we are telling that whoever wants to use TodoBusinessService needs to pass TodoDataService implementation. Now TodoBusinessService is no longer dependent on TodoDataServiceImpl class. TodoDataServiceImpl class can implement TodoDataService and provide implementation for retrieveTodos(). Then if anyone wants to use TodoBusinessService he will then pass TodoDataServiceImpl while creating TodoBusinessService

(**doubt - what if we are Autowiring TodoBusinessService as well, how can we pass TodoDataService implementation then? - I think, Due to the @Component annotation on TodoBusinessService we don't have to instantiate it. If we autowire TodoBusinessService, Spring will search for it, then it will find new dependency of TodoDataService, it will then find the implementation class for this, once found it will autowire it in TodoBusinessService and now we have TodoBusinessService complete and ready to be used.)

Example-2:

```
@Component
public class ComplexAlgorithmImpl {

    @Autowired
    private SortAlgorithm sortAlgorithm;

    public ComplexAlgorithmImpl(SortAlgorithm sortAlgorithm){
    }
}
```

```

55         this.sortAlgorithm = sortAlgorithm;
56     }
57     ...
58
59     public interface SortAlgorithm {
60         public int[] sort(int[] numbers);
61     }
62
63
64
65     public class QuickSortAlgorithm implements SortAlgorithm {
66
67
68     public class BubbleSortAlgorithm implements SortAlgorithm {
69
70
71     Now here at the time of creating ComplexAlgorithmImpl, user can inject
72     either QuickSortAlgorithm or BubbleSortAlgorithm according to his need.
73     ComplexAlgorithmImpl is no longer dependent on specific implementation.

```

This Loose Coupling.

2. What is dependency?

In the above code TodoDataService is dependency for TodoBusinessService and SortAlgorithm is dependency for ComplexAlgorithmImpl

3. What is Dependency Injection?

```

ComplexAlgorithmImpl binarySearch = new ComplexAlgorithmImpl(new
QuickSortAlgorithm());    //We are doing this explicitly

```

We use Spring Framework to instantiate beans and wire dependencies

```

@Component
public class ComplexAlgorithmImpl {
    @Autowired
    private SortAlgorithm sortAlgorithm;
    ...

```

In this case when spring is creating bean for ComplexAlgorithmImpl, it will detect the SortAlgorithm dependency because of Autowired annotation, and it will start finding possible matches to resolve that dependency. And as soon as it finds QuickSortAlgorithm, it will instantiate it and inject in ComplexAlgorithmImpl. This is dependency injection.

So spring searches for beans and once it has found the appropriate bean it will autowire it.

Dependency Injection is process where spring identifies the dependencies, starts searching then and once found it will instantiate them and autowire them.

4. What is Inversion Of Control?

```

public class ComplexAlgorithmImpl {
    BubbleSortAlgorithm bubbleSortAlgorithm = new BubbleSortAlgorithm();
    ...

```

In above case, the ComplexAlgorithmImpl is responsible to create the dependency i.e. BubbleSortAlgorithm. So the control is with ComplexAlgorithmImpl. This tightly coupled.

```

@Component
public class ComplexAlgorithmImpl {
    @Autowired
    private SortAlgorithm sortAlgorithm;
    ...

```

Here we are not instantiating the SortAlgorithm or dependency. Here the control or responsibility of creating the dependency goes to the user(who will be using ComplexAlgorithmImpl class) or to framework (Spring). So Spring will take control, search the dependencies and inject.

So now the control has been inversed as it was in earlier case. This is inversion of control.

5. What is Autowiring?

```
@Component
public class ComplexAlgorithmImpl {

    @Autowired
    private SortAlgorithm sortAlgorithm;
    ...
}
```

When we write @Autowired, Spring framework needs to find the bean which would match this dependency and then it would have to populate the dependency in there. This process is called Autowiring.

6. What are the important roles of an IOC Container? What are Bean Factory and Application Context? Can you compare Bean Factory with Application Context?

- Find the beans
- Wire Dependencies
- Manage Lifecycle of the bean

Example-1:

```
@Component
public class ComplexAlgorithmImpl {

    @Autowired
    private SortAlgorithm sortAlgorithm;
    ...
}

@Component
public class QuickSortAlgorithm implements SortAlgorithm {

    public interface SortAlgorithm {
        public int[] sort(int[] numbers);
    }
}
```

In the above code IOC container will first identify the class with annotation @Component. This will indicate it that these are the beans it needs to create. This is step one.

Second is to autowire dependencies.

The two terms that are related to IOC container are Application Context and Bean Factory.

Bean Factory is the most basic version of IOC container that spring provides.

Bean Factory, the basic things of IOC container it will be able to that - find beans, wire dependencies, manage life cycle of bean.

Application Context is much more advance kind of IOC Container.

Application Context = Bean Factory + Spring's AOP features + I18n capabilities + WebApplicationContext for web applications, etc

7. How do you create an application context with Spring?

We can define it using an XML or we can define it using an annotation

@Configuration.

Using XML -

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:aop="http://www.springframework.org/schema/aop"
       xmlns:context="http://www.springframework.org/schema/context"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xsi:schemaLocation="http://www.springframework.org/schema/beans
                           http://www.springframework.org/schema/beans/spring-beans-3.0.xsd
                           http://www.springframework.org/schema/tx
                           http://www.springframework.org/schema/tx/spring-tx-3.0.xsd
                           http://www.springframework.org/schema/context
                           http://www.springframework.org/schema/context/spring-context-3.0.xsd
                           http://www.springframework.org/schema/aop
                           http://www.springframework.org/schema/aop/spring-aop.xsd"
       >
    </beans>
    ApplicationContext context =
        new ClassPathXmlApplicationContext(
            new String[] {"BusinessApplicationContext.xml",
                          "Other-Configuration.xml"});
```

Using Annotation -

```
@Configuration //Just by this annotation we have defined
application context.
class SpringContext {
}

ApplicationContext ctx =
    new AnnotationConfigApplicationContext(
        SpringContext.class);
```

We can also create ApplicationContext in our Unit tests -

```
@RunWith(SpringJUnit4ClassRunner.class)
@ContextConfiguration(classes = JavaTestContext.class)
//JavaTestContext is our java annotation configuration
public class DependencyInjectionJavaContextExamples {
    ...

    @RunWith(SpringJUnit4ClassRunner.class)
    @ContextConfiguration(locations = { "/TestContext.xml" })
    //TestContext.xml is our xml configuration
    public class TodoBusinessTest {
        ...
    }
}
```

8. How does Spring know where to search for Components or Beans?
What is a component scan?
How do you define a component scan in XML and Java Configuration?
How is it done with Spring Boot?

Java Configuration -

```
@Configuration
@ComponentScan(basePackages = {
    "com.in28minutes.spring.example1.businessservice",
    "com.in28minutes.spring.example1.dataservice.stub" })
class SpringContext {
}
}
```

XML Configuration -

```

229     <?xml version="1.0" encoding="UTF-8" standalone="no"?>
230     <beans xmlns="http://www.springframework.org/schema/beans"
231           xmlns:aop="http://www.springframework.org/schema/aop"
232           xmlns:context="http://www.springframework.org/schema/context"
233           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
234           xsi:schemaLocation="http://www.springframework.org/schema/beans
235                               http://www.springframework.org/schema/beans/spring-beans-3.0.xsd
236                               http://www.springframework.org/schema/tx
237                               http://www.springframework.org/schema/tx/spring-tx-3.0.xsd
238                               http://www.springframework.org/schema/context
239                               http://www.springframework.org/schema/context/spring-context-3.0.xsd
240                               http://www.springframework.org/schema/aop
241                               http://www.springframework.org/schema/aop/spring-aop.xsd"
242           >
243
244         <context:component-scan base-package="com.in28minutes.example"/>
245
246     </beans>

```

Spring Boot -

```

246     package com.in28minutes.spring.basics.springin5steps;
247
248     @SpringBootApplication
249     public class SpringIn5StepsApplication {
250     ...
251
252     -----
253
254     package com.in28minutes.spring.basics.springin5steps;
255
256     @RunWith(SpringRunner.class)
257     @SpringBootTest
258     public class SpringIn5StepsApplicationTests {
259
260
261     Annotations @SpringBootApplication and @SpringBootTest will automatically
262     initiate a scan on the package where they are in and also the sub-packages.

```

9. What does @Component signify?
 What does @Autowired signify?
 What's the difference between @Controller, @Component, @Repository and @Service annotations in Spring?

@Component - Generic Component. signifies that this is a bean and it needs to be managed by Spring.

@Autowired - Spring should find the matching bean and wire the dependency in.

@Service - Business Service Facade

@Controller - Controller in MVC pattern

@Repository - encapsulating storage, retrieval, and search behavior typically from a relational database

We can use @Component on any layer i.e. Web, Business, or Data. So @Component is generic.

@Controller is specific to Web layer

@Repository is specific to Data layer

@Service is specific to Business layer

There also some specific features which Spring has attached with these annotations, like when every a JDBC exception occurs, due to @Repository annotation it will be translated to Spring specific exception.

```

284
285 10. What is the default scope of a bean?
286 Are Spring beans thread safe?
287 What are the other scopes available?
288 How is Spring's singleton bean different from Gang of Four Singleton Pattern?
289
290 When we create a bean we can specify any of the below scopes -
291     singleton - One instance per Spring Context. When we create a
292     ApplicationContext then there is only one instance of that bean.
293     prototype - New bean whenever requested. In a single ApplicationContext if we
294     have 100 requests, then we will create 100 different beans.
295     request - One bean per HTTP request. Web-aware Spring ApplicationContext.
296     Applicable only in case of WebApplicationContext.
297     session - One bean per HTTP session. Web-aware Spring ApplicationContext.
298     Applicable only in case of WebApplicationContext. Eg. - store user-specific
299     details.
300
301 (Maintain details of user across multiple request, then we create a session)
302
303 As by default scope of bean is singleton i.e. only one instance, so by default it
304 is not thread safe as multiple threads can act on single bean at the same time.
305
306 Notes:
307     - The singleton scope is the default scope in Spring.
308     - The Gang of Four defines Singleton as having one and only one instance per
309     ClassLoader.
310     - However, Spring singleton is defined as one instance of bean definition per
311     container (per ApplicationContext, if we have multiple ApplicationContext
312     inside same JVM then we will have multiple instance of that bean).
313
314 Examples:
315
316 @RequestScope
317 @Component
318 public class RequestScopedBean {
319     ...
320     -----
321
322 @SessionScope
323 @Component
324 public class SessionScopedBean {
325     ...
326     -----
327
328 <bean id="someBean" class="com.in28minutes.SomeBean"
329       scope="prototype"/>
330
331
332 11. What are the different types of dependency injections?
333 What is setter injection?
334 What is constructor injection?
335 How do you choose between setter and constructor injections?
336
337 There are two types of dependency injections - Setter and Constructor injections.
338
339 Setter Injection:
340
341     @Component
342     public class TodoBusinessService {
343
344         TodoDataService dataService;
345
346         @Autowired
347         public void setDataService(TodoDataService dataService) {
348             this.dataService = dataService;
349         }
350     }

```

```

344     ...
345
346     -----
347
348     //Through Reflection
349     @Component
350     public class TodoBusinessService {
351
352         @Autowired
353         TodoDataService dataService;
354         ...
355
356         Setter inject happens through a setter.
357

```

Constructor Injection:

```

359     @Component
360     public class TodoBusinessService {
361
362         TodoDataService dataService;
363
364
365         @Autowired
366         public TodoBusinessService(TodoDataService dataService) {
367             super();
368             this.dataService = dataService;
369         }
370

```

Here Spring will constructor to do wiring, it will call constructor.

Constructor vs Setter Injection

<https://docs.spring.io/spring/docs/current/spring-framework-reference/htmlsingle/>
The Spring team generally advocates constructor injection as it enables one to implement application components as immutable objects and to ensure that required dependencies are not null. (means Spring recommends to use constructor injection)

Constructor Injection for Mandatory Dependencies (mandatory dependencies i.e. that that need for sure)

Setter Injection for Optional Dependencies.

Furthermore constructor-injected components are always returned to client (calling) code in a fully initialized state.

As a side note, a large number of constructor arguments is a bad code smell.

12. What are the different options available to create Application Contexts for Spring?
What is the difference between XML and Java Configurations for Spring?
How do you choose between XML and Java Configurations for Spring?

XML:

```

390     <?xml version="1.0" encoding="UTF-8" standalone="no"?>
391     <beans xmlns="http://www.springframework.org/schema/beans"
392         xmlns:aop="http://www.springframework.org/schema/aop"
393         xmlns:context="http://www.springframework.org/schema/context"
394         xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
395         xsi:schemaLocation="http://www.springframework.org/schema/beans
396             http://www.springframework.org/schema/beans/spring-beans-3.0.xsd
397             http://www.springframework.org/schema/tx
398             http://www.springframework.org/schema/tx/spring-tx-3.0.xsd
399             http://www.springframework.org/schema/context
400             http://www.springframework.org/schema/context/spring-con
401             text-3.0.xsd
402             http://www.springframework.org/schema/aop
403             http://www.springframework.org/schema/aop/spring-aop.xsd
404         ">
405
406     </beans>

```

In between <beans> tag we will define all the beans we want and we can launch it

using below code:

```
ApplicationContext context = new ClassPathXmlApplicationContext(new String[]  
{"BusinessApplicationContext.xml", "Other-Configuration.xml"});
```

Java:

```
@Configuration  
class SpringContext {  
}
```

We need to put @Configuration, and then we can define beans using @Bean annotation and we can launch them using below code:

```
ApplicationContext ctx = new  
AnnotationConfigApplicationContext(SpringContext.class);
```

With Spring Boot, we are slowly moving towards complete Java Configuration.

13. How does Spring do Autowiring?

What are the different kinds of matching used by Spring for Autowiring?

Autowiring:

- byType
- byName
- constructor - similar to byType, but through constructor. It finds matching constructor by type.

by Type - Class or Interface:

```
@Component  
public class ComplexAlgorithmImpl {  
  
    @Autowired  
    private SortAlgorithm sortAlgorithm;  
    ...  
-----  
  
public interface SortAlgorithm {  
    public int[] sort(int[] numbers);  
}  
  
-----  
  
@Component  
public class QuickSortAlgorithm implements SortAlgorithm {  
  
    -----
```

by Name:

```
@Component  
public class ComplexAlgorithmImpl {  
  
    @Autowired  
    private SortAlgorithm quickSortAlgorithm;  
    ...  
-----  
  
public interface SortAlgorithm {  
    public int[] sort(int[] numbers);  
}  
  
-----
```

```

466         @Component
467         public class QuickSortAlgorithm implements SortAlgorithm {
468
469             -----
470
471         @Component
472         public class BubbleSortAlgorithm implements SortAlgorithm {
473
474             -----

```

476 Constructor Injection:

```

477
478         @Component
479         public class TodoBusinessService {
480
481             TodoDataService dataService;
482
483             @Autowired
484             public TodoBusinessService(TodoDataService dataService) {
485                 super();
486                 this.dataService = dataService;
487             }
488
489

```

490 14. How do you debug problems with Spring Framework?

- 491 - NoUniqueBeanDefinitionException
- 492 - NoSuchBeanDefinitionException

493 What is @Primary?

494 What is @Qualifier?

497 No matching Components:

```

498
499         @Component
500         public class ComplexAlgorithmImpl {
501
502             @Autowired
503             private SortAlgorithm sortAlgorithm;
504             ...
505
506             -----
507
508         public interface SortAlgorithm {
509             public int[] sort(int[] numbers);
510         }
511
512         -----
513
514         public class QuickSortAlgorithm implements SortAlgorithm {
515
516             -----
517
518         public class BubbleSortAlgorithm implements SortAlgorithm {
519

```

520 In above code we don't have @Component defined to QuickSortAlgorithm and BubbleSortAlgorithm. So spring won't find any beans. In such cases it will throw a NoSuchBeanDefinitionException.

521 In some cases, it might happen that you have defined @Component to those classes, but have not defined @ComponentScan well. This might also result in same exception - NoSuchBeanDefinitionException.

523 Typically problems:

- 524 - @Component missing
- 525 - or @ComponentScan not defined properly

528 Exception - Two matching Components:

```

529
530         @Component

```

```

531     public class ComplexAlgorithmImpl {
532
533         @Autowired
534         private SortAlgorithm sortAlgorithm;
535         ...
536
537         -----
538
539     public interface SortAlgorithm {
540         public int[] sort(int[] numbers);
541     }
542
543     -----
544     @Component
545     public class QuickSortAlgorithm implements SortAlgorithm {
546
547         -----
548         @Component
549         public class BubbleSortAlgorithm implements SortAlgorithm {
550
551             Now here, spring will find ambiguity, first it will look by type, it will find
552             two class of type SortAlgorithm - QuickSortAlgorithm and BubbleSortAlgorithm.
553             So it will next look by name - sortAlgorithm, but again it won't find any bean
554             with name SortAlgorithm of type SortAlgorithm. It will throw exception -
555             NoUniqueBeanDefinitionException.
556             We can solve this by naming it properly - by using autowire by name.
557             Other option is to use @Primary.
558             Other option is to use @Qualifier.
559
560             Primary:
561
562             @Component
563             @Primary
564             public class BubbleSortAlgorithm implements SortAlgorithm {
565                 ...
566
567             We can say BubbleSortAlgorithm is our primary class. So now if spring finds
568             ambiguity, it will use BubbleSortAlgorithm first.
569
570             Qualifier
571
572             @Component
573             public class ComplexAlgorithmImpl {
574
575                 @Autowired
576                 @Qualifier("mainAlgorithm")
577                 private SortAlgorithm sortAlgorithm;
578                 ...
579
580                 -----
581                 @Component
582                 @Qualifier("mainAlgorithm")
583                 public class BubbleSortAlgorithm implements SortAlgorithm {
584                     ...
585
586                 So need to specify @Qualifier on the dependency and give it a name. And we also
587                 need to specify same Qualifier name on the Component which we want to autowire
588                 in case of ambiguity.
589
590             15. What is CDI (Contexts and Dependency Injection)?
591             Does Spring Support CDI?
592             Would you recommend to use CDI or Spring Annotations?
593
594             CDI:
595             CDI is Java EE Dependency Injection Standard (JSR-330), just like JPA is a
596             standard. CDI defines some annotation/APIs for Dependency Injection. This uses

```

some different annotation than Spring. Like below for Spring's @Autowired it uses @Inject annotation and so on.

- @Inject (@Autowired)
- @Named (@Component & @Qualifier) - @Named means we want CDI framework to manage this bean
- @Singleton (Defines a scope of Singleton)

This is just like JPA and Hibernate. JPA is a standard and Hibernate follows JPA. JPA has different annotations which Hibernate supports with some different annotations.

Same way CDI is standard which is supported by Spring.

We can use either of these.

16. What are the major features in different versions of Spring?

What are new features in Spring Framework 4.0?

What are new features in Spring Framework 5.0?

Notes

Spring 2.5 made annotation-driven configuration possible.

Spring 3.0 made great use of the Java 5 improvements in language.

Spring 4.0

First version to fully support Java 8 features.

Minimum version of Java to use Spring 4 is Java SE 6.

Introduced @RestController annotation

Spring 4.1 supports JCache (JSR-107) annotations

Spring 5.0

Functional web framework

Support for Jigsaw (Java Modularity)

Support for reactive programming

Support for Kotlin

17. What are important Spring Modules?

file:///C:/Users/inarajp/Desktop/temp/spring-interview-guide-master/spring-interview-guide-master/1.presentation/images/SpringModules.png

Core Container Modules - Beans, Core, Context, SpEL - Bean management, Autowiring, Dependency injection, ApplicationContext, Spring core, etc.

SpEL - Spring Expression Language

Data Access/Integration module - JDBC, ORM, OXM, JMS, Transactions

Spring has its own JDBC framework called Spring-JDBC

ORM - Object Relation Mapping, thus has good integration with framework like Hibernate

OXM - Object XML Mapping module, thus has good integration with framework like JAXB

JMS - Java Messaging Services

Transactions - Build in support for Transactions, can manage transactions for JPA, JDBC, Hibernate, etc.

Web module - WebSocket, Servlet, Portlet, Web

Spring has web MVC framework of its own called - Spring MVC - Can develop web applications easily, support for REST

Supports - Servlets, Portlets, Web Socket

649
650 Cross cutting concerns - Logging, exception handling, etc. These are concerns for
all the layers present in the application.

651 AOP can be used to implement cross cutting concerns. Spring provides a basic aspect
oriented programming module of its own, also spring has good support for AOP
frameworks like Aspectj.

652
653 Spring-Test module - it helps use to write unit test and integration test.

654
655 So when we say there a new relese of spring with new version, there will be a new
release for all these modules with that version. Modules will have the same
versions as the base spring framework.

656
657

658 18. What are important Spring Projects?

659
660 All the Spring Modules have the same release version as the base Spring framework.
So they are like part of Spring framework.

661
662 Spring Projects provide solutions to different problems.

663
664 Spring Projects:

- 665 - Spring Boot
- 666 - Spring Cloud
- 667 - Spring Data
- 668 - Spring Integration
- 669 - Spring Batch
- 670 - Spring Security
- 671 - Spring HATEOAS
- 672 - Spring Web Services
- 673 - Spring Session

674
675 Spring Boot - Popular framework to develop microservices. Very helpful to develop
the applications quickly. They have feature like - Startup projects, auto
configurations, accuators, etc.

676
677 Spring Cloud - Cloud navtive application, dynamically connect them, deploy them,
etc.

678
679 Spring Data - Can connect to variety of databases.

680
681 Spring Integration - Addresses problems related to application integration.

682
683 Spring HATEOAS - In rest it might not be sufficient to just return the data. You
would also want to return the related links, that would help the consumer to
understand where to go from here. Spring-HATEOAS will help us do that easily.

684
685 There are many other Spring projects as well.

686
687

688 19. What is the simplest way of ensuring that we are using single version of all Spring
related dependencies?

689
690 If we are making use of different modules, then we don't want to specify same
versions to all.

691
692 BOM (Bill Of Material dependency) - Declares dependency version for all the spring
modules.

693
694 Use a BOM (Bill Of Material dependency):

695
696 <dependencyManagement>

- 697 <dependencies>
- 698 <dependency>
- 699 <groupId>org.springframework</groupId>
- 700 <artifactId>spring-framework-bom</artifactId>
- 701 <version>5.0.0.RELEASE</version>
- 702 <type>pom</type>
- 703 <scope>import</scope>

```

704         </dependency>
705     </dependencies>
706 </dependencyManagement>
707
708 -----
709
710 <dependencies>
711     <dependency>
712         <groupId>org.springframework</groupId>
713         <artifactId>spring-context</artifactId>
714     </dependency>
715     <dependency>
716         <groupId>org.springframework</groupId>
717         <artifactId>spring-web</artifactId>
718     </dependency>
719 </dependencies>
720
721 https://www.baeldung.com/spring-maven-bom
722
723

```

20. Name some of the design patterns used in Spring Framework?

Design Patterns in Spring:

- Front Controller pattern - Dispatcher Servlet - all browser request will first go to Dispatcher Servlet.
- Prototype - Beans
- Dependency Injection
- Factory Pattern - Bean Factory & Application Context
- Template Method
org.springframework.web.servlet.mvc.AbstractController, JdbcTemplate, etc

21. What are some of the important Spring annotations you have used?

Annotations:

- @Component, @Service, @Repository, @Controller
- @Autowired
- @Primary
- @Qualifier
- @Configuration

22. What do you think about Spring Framework?

Why is Spring Popular?

Can you give a big picture of the Spring Framework?

- Architecture - Flexible & No Restrictions
- Design - Loosely Coupled
- Code - Easy Unit Testing
- Features - Dependency Injection, IOC Container (Bean Factory & Application Context), Auto wiring, Component Scan
- Spring Modules
- Spring Projects

Spring has good support for struts, jsps, AOP, Freemarker, etc. It integrates well with all of these. This is architectural flexibility. It doesn't restrict our choices.

Whenever we develop a loosely coupled application with Spring it's easy to unit test it.

23. MVC - What is Model 1 architecture?

What is Model 2 architecture?

What is Model 2 Front Controller architecture?

Model 1 is most basic. In this when request comes from browser the request directly goes to JSPs. (in html action we will put .jsp page). All logic will be in JSP page - like calling the DB, populating the model, creating the view, etc everything happens in JSPs. There are no Servlets. Therefore this resulted into very complex

JSPs, difficult to maintain.

Hence we migrated to Model 2 architecture, where request first goes to a Servlet and Servlet makes sure that it gets all the data from db and model is ready and then it redirects it to view. And view makes use of model and display it in the view. So Servlets acted as a Controller here.

Future enhancement of MVC-pattern was Model 2 Front Controller. Here request instead of going to Servlet, will first go to Front Controller. Front controller gets all the request, it makes sure that the response is ready and sends it back to the browser. Now we have one place to control everything that comes from the outside world. So if we want to make our application secure then we will implement security at the Front Controller level. Thus if our Front controller is secure our entire application below it will also be secure.

Front Controller based on the request will identify the right Servlet and then when Servlet will execute (make calls to db, populate the models) and return the models to Front Controller. Front Controller will then identify which view to render. And once the view is rendered it will send that information back to browser.

Check diagram at -

C:\Users\inarajp\Desktop\temp\spring-interview-guide-master\spring-interview-guide-master\1.presentation\images

24. Can you show an example controller method in Spring MVC?

Can you explain a simple flow in Spring MVC?

What is a ViewResolver?

What is Model?

What is ModelAndView?

What is a RequestMapping?

Controller Method:

```
@RequestMapping(value = "/list-todos", method = RequestMethod.GET)
public String listTodos(ModelMap model) {
    model.addAttribute("todos", service.retrieveTodos(retrieveLoggedInUserName()));
    return "list-todos";
}
```

ViewResolver:

```
<bean class =
"org.springframework.web.servlet.view.InternalResourceViewResolver">
    <property name="prefix">
        <value>/WEB-INF/views/</value>
    </property>
    <property name="suffix">
        <value>.jsp</value>
    </property>
</bean>
```

Model vs ModelAndView:

```
@RequestMapping(value = "/", method = RequestMethod.GET)
public String showLoginPage(ModelMap model) {
    model.put("name", "in28Minutes");
    return "welcome";
}

@RequestMapping(value = "/", method = RequestMethod.GET)
public ModelAndView showLoginPage() {
    ModelAndView mv = new ModelAndView();
    mv.addObject("name", "in28Minutes");
    mv.setViewName("welcome");
}
```

Check diagram.

DispatcherServlet knows about all the Controllers, all the urls that are mapped in those controllers, etc. It knows all the handler mapping. Controller then will populate the model. It will then return name of the view back to DispatcherServlet. Then DispatcherServlet asks ViewResolver to map the view name to the physical view page. ViewResolver will then add a prefix and suffix and map return to DispatcherServlet. DispatcherServlet will then pass the model to view, which will render and this rendered view will be sent as response by DispatcherServlet.

25. What is Dispatcher Servlet?

How do you set up Dispatcher Servlet?

```
<servlet>
  <servlet-name>dispatcher</servlet-name>
  <servlet-class>org.springframework.web.servlet.DispatcherServlet</servlet-class>
  <init-param>
    <param-name>contextConfigLocation</param-name>
    <param-value>/WEB-INF/todo-servlet.xml</param-value>
    //location of spring context (beans).
  </init-param>
  <load-on-startup>1</load-on-startup>
</servlet>

<servlet-mapping>
  <servlet-name>dispatcher</servlet-name>
  <url-pattern>/</url-pattern>                                //all
  request will go to dispatcher
</servlet-mapping>
```

In Spring boot we don't have to do this configuration at all. Because spring boot has a feature called Auto-Configuration, where in as soon as we add spring-web-mvc-jar in a classpath, it would know that you are developing a web application and it will auto configure a DispatcherServlet for us.

26. What is a form backing object?

How is validation done using Spring MVC?

What is BindingResult?

How do you map validation results to your view?

What are Spring Form Tags?

form backing form is basically the server side representation of the form.

Show New Todo Page:

```
// This mapping method is called for first time display of the form. Thus form
fields will be filled with default values or will be empty.
```

```
@RequestMapping(value = "/add-todo", method = RequestMethod.GET)
public String showTodoPage(ModelMap model) {
    model.addAttribute("todo", new Todo(0, retrieveLoggedInUserName(), "", new
    Date(), false));           //todo => form backing object
    return "todo";
}
```

todo.jsp:

```
<form:form method="post" commandName="todo">
  //commandName="todo" => mapping the form backing object.
  <fieldset>
    <form:label path="desc">Description</form:label>
    <form:input path="desc" type="text"/>
    <form:errors path="desc"/>
  </fieldset>
  <fieldset>
    <form:label path="targetDate">Target Date</form:label>
    <form:input path="targetDate" type="text" />
    <form:errors path="targetDate"/>
```

```

873         </fieldset>
874         <input type="submit" value="Submit" />
875     </form:form>

```

877 Add Todo:

```

878     @RequestMapping(value = "/add-todo", method =
879     RequestMethod.POST) //value = "/add-todo", is for POST, above
was for GET. When submit is pressed POST will happen.
880     public String addTodo(ModelMap model, @Valid Todo todo, BindingResult result) {
881         if (result.hasErrors()) {
882             return "todo";
883         }
884
885         service.addTodo(retrieveLoggedInUserName(), todo.getDesc(), new Date(), false);
886
887         model.clear();
888         return "redirect:list-todos";
889     }
890 }

```

891 Todo.java:

```

892     public class Todo {
893
894         private int id;
895
896         private String user;
897
898         @Size(min = 6, message = "Enter atleast 6 characters")
899         private String desc;
900
901         ...
902
903     }
904
905

```

For validation we need to use Java validation API, hibernate validator is implementation of Java validation API. @Size and @Valid. We add validation on beans. @Valid will validate whatever validations we have added on the bean. Validation gets invoked and the result of validation gets stored into BindingResult. We display validation error on jsp using spring's <form:errors tag.

906 27. What is a Path Variable?

907 What is a Model Attribute?

908 What is a Session Attribute?

909 Path Variable:

```

910     URI - http://localhost:8080/todos/1
911
912     @RequestMapping(value = "/todos/{id}")
913     public Todo retrieveTodo(@PathVariable int id) {
914         return service.retrieveTodo(id);
915     }
916
917

```

918 Model Attribute:

```

919     @ModelAttribute
920     public void addAttributes(Model model) {
921         model.addAttribute("options", Arrays.asList("Option 1", "Option 2", "Option
922         3" ));
923     }
924
925

```

- Indicates the purpose of that method is to add one or more model attributes.
- Invoked before @RequestMapping methods.
- Used to fill the model with commonly needed attributes
- Drop down values for form
- It will be available to all the methods in the controller

926 @SessionAttributes:

```

936
937     List the names of model attributes which should be transparently stored in the
          session or some conversational storage.
938
939     @SessionAttributes("name")
940     public class TodoController {
941         ...
942
943     Example name of logged in user.
944
945     When developing web applications, we often need to refer to the same attributes
          in several views. A good location to store those attributes is in the user's
          session.
946
947
948     @SessionAttributes or @SessionAttribute example:
949
950         @SessionAttributes annotation is used to store the model attribute in the
          session. This annotation is used at controller class level.
951
952         @SessionAttributes("user")
953         public class LoginController {
954
955             @ModelAttribute("user")
956             public User setUpUserForm() {
957                 return new User();
958             }
959         }
960         In the above code snippet, the model attribute 'user' will be added to the
          session if the name attribute of the @ModelAttribute and @SessionAttributes
          annotations is same.
961
962         @SessionAttribute annotation is used to retrieve the existing attribute from
          session that is managed globally and it is used at method parameter as shown
          follows.
963
964         @GetMapping("/info")
965         public String userInfo(@SessionAttribute("user") User user) {
966             //...
967             //...
968             return "user";
969         }
970
971         https://www.boraji.com/spring-mvc-4-sessionattributes-example
972
973
974 28. What is a init binder?
975     How do you set default date format with Spring?
976
977     Setting default format of date. We want to set a format for the entire application.
          We don't want to keep setting date format for all the fields in the application.
978
979     @InitBinder
980     protected void initBinder(WebDataBinder binder) {
981         SimpleDateFormat dateFormat = new SimpleDateFormat("dd/MM/yyyy");
982         binder.registerCustomEditor(Date.class, new CustomDateEditor(dateFormat, false));
983     }
984
985
986     Suppose we have a form and on submission of the form we don't want spring to bind a
          specific field in an object, then we use initBinder.
987
988     @InitBinder
989     protected void initBinder(WebDataBinder binder) { //name of function can be
          anything, by its parameter should be WebDataBinder and with annotation @InitBinder
990
991         binder.setDisabllowedFields(new String[] {"studentMobile"});
          //studentMobile will not be binded by spring
992     }

```

```

993 @RequestMapping(value...)
994 public ModelAndView submit(@ModelAttribute("student") Student stud){
995     //studentMobile won't be binded here..
996     ...
997 }
998
999 Above is basic level example.

```

The concept of property editor -

Suppose we have -

```

1005 class Student{
1006     ....
1007
1008     Date studentDOB;
1009     ....
1010 }

```

if user inputs date in format 2010/10/10 Spring will be able to bind it in Student object. If user enters date in format 2010****10****10 then spring won't bind it, it will give error.

So question is how to allow user to provide date in some customized format of your choice, say --> yyyy****MM****dd?

And answer is using property editor concept provided by spring.

```

1016 @InitBinder
1017 protected void initBinder(WebDataBinder binder) {
1018
1019     binder.setDisabllovedFields(new String[] {"studentMobile"});
1020
1021     SimpleDateFormat dateFormat = new SimpleDateFormat("yyyy****MM****dd");
1022     binder.registerCustomEditor(Date.class, "studentDOB", new
1023         CustomDateEditor(dateFormat, false));
1024
1025     //For above line - // We are registering our own format with WebDataBinder. We
1026     //are telling Spring MVC that, hey when whenever you are performing binding for
1027     //Date.class and you will be performing it for field studentDOB then you simply
1028     //for this - dateFormat format for performing that task.
1029 }

```

Spring mvc internally uses property editors to perform data binding tasks. What this means is Spring mvc has many classes which it calls as a property editor class and CustomDateEditor is one of them. Other examples are FileEditor, ClassEditor, CustomNumberEditor, etc. Spring MVC uses these classes in order to perform type conversion while data binding. We can use a particular property editor class in order to customize data binding for a particular data type.

29. How do you implement common logic for Controllers in Spring MVC?

What is a Controller Advice?

What is @ExceptionHandler?

How to handle exceptions for web applications?

What are the important things to think about when implementing Exception Handling?

How do you implement Specific Error Handling for a Spring MVC Controller?

ExceptionHandler:

```

1039 @ControllerAdvice //For all the controllers present in
1040 application
1041 public class ExceptionController {
1042
1043     private Log logger = LoggerFactory.getLog(ExceptionController.class);
1044
1045     @ExceptionHandler(value = Exception.class) //@ExceptionHandler is the advice which
1046     //we are handling in @ControllerAdvice. We can directly put this in a controller to
1047     //make it controller specific.
1048     public String handleException(HttpServletRequest request, Exception ex) {

```

```

1046         logger.error("Request " + request.getRequestURL() + " Threw an Exception", ex);
1047         return "error";
1048     }
1049 }
1050
1051

```

30. Why is Spring MVC so popular?

Spring MVC:

- Clear Separation of Concerns
 - Dispatcher Servlet
 - View Resolver
 - View
 - Model

All these are completely independent of one another.
 Helps use to develop the web application easily
 As well as Unit test it easily
 It is not only used to develop web applications but it is also used to develop RESTfull webservices.

31. What is Spring Boot?

What are the important Goals of Spring Boot?

What are the important Features of Spring Boot?

Why Spring Boot?

Spring based applications have a lot of configuration.
 When we use Spring MVC, we need to configure component scan, dispatcher servlet, a view resolver, web jars(for delivering static content) among other things.
 World is moving towards Microservices.
 We do not have a lot of time to set up 100 microservices.

Spring Boot Goals:

- Quick Start to Spring
- Be opinionated
- Non functional features
- No code generation

Spring Boot Features:

- Auto Configuration -
 - eg - if spring boot find spring mvc jar in classpath then it will assume that we are developing a web application and it will automatically configure all the required things like dispatcher servlet, view resolver, etc. Same way if we add a JPA jar, then we get auto configuration related to connecting the database.
- Spring Boot Starter Projects
- Spring Boot Actuator - helps in monitoring our application
- Embedded Server - with spring boot application we can embed a server inside our deployable jar. Servers like tomcat, jetty can be included into our jar file and when we run application on the server then we don't need server installed separately.

32. Compare Spring Boot vs Spring?

Compare Spring Boot vs Spring MVC?

Spring:

Most important feature of Spring Framework is Dependency Injection. At the core of all Spring Modules is Dependency Injection or IOC Inversion of Control.

@RestController

```
public class WelcomeController {
```

```
    private WelcomeService service = new WelcomeService();
```

```
    @RequestMapping("/welcome")
```

```

1104         public String welcome() {
1105             return service.retrieveWelcomeMessage();
1106         }
1107     }
1108

```

With Spring:

```

1110
1111     @Component
1112     public class WelcomeService {
1113         //Bla Bla Bla
1114     }
1115
1116     @RestController
1117     public class WelcomeController {
1118
1119         @Autowired
1120         private WelcomeService service;
1121
1122         @RequestMapping("/welcome")
1123         public String welcome() {
1124             return service.retrieveWelcomeMessage();
1125         }
1126     }
1127

```

Problems Spring Solves:

```

1129     Problem 1 : Duplication/Plumbing Code    --like very less code for jdbc or db
1130     Problem 2 : Good Integration with Other Frameworks.    --like if we want to
                        integrate struts, hibernate, JMS, etc

```

Spring MVC:

```

1133     Spring MVC Framework provides decoupled way of developing web applications.
        With simple concepts like Dispatcher Servlet, ModelAndView and View Resolver,
        it makes it easy to develop web applications.

```

Spring Boot:

```

1136     - Eliminates all configuration needed by Spring and Spring MVC and auto
        configures it
1137     - No need for @ComponentScan. Default Component Scan.
1138     - No need to configure DispatcherServlet
1139     - No need to configure a Data Source, Entity Manager Factory or Transaction
        Manager.

```

Spring Boot Thinking:

```

1142     Can we bring more intelligence into this? When a spring mvc jar is added into
        an application, can we auto configure some beans automatically?

```

Spring Boot looks at -

```

1145     Frameworks available on the CLASSPATH
1146     Existing configuration for the application.
1147     Based on these, Spring Boot provides Auto Configuration.

```

33. What is the importance of @SpringBootApplication?

@SpringBootApplication is replaced with -

```

1154     @SpringBootConfiguration
1155     @EnableAutoConfiguration
1156     @ComponentScan
1157     public @interface SpringBootApplication {
1158         .....

```

34. What is Auto Configuration?

How can we find more information about Auto Configuration?

Spring Boot looks at :

```

1166     a) Frameworks available on the CLASSPATH

```

1167 b) Existing configuration for the application. Based on these, Spring Boot provides basic configuration needed to configure the application with these frameworks. This is called Auto Configuration.

1168
1169 Application Startup Log:
1170 Mapping servlet: 'dispatcherServlet' to [/]
1171
1172 Mapped "[[/error]]" onto public org.springframework.http.ResponseEntity
1173 <java.util.Map<java.lang.String, java.lang.Object>>
1174 org.springframework.boot.autoconfigure.web.
1175 BasicErrorController.error(javax.servlet.http.HttpServletRequest)
1176
1177 Mapped URL path [/webjars/ * *] onto handler of type
1178 [class org.springframework.web.servlet.resource.ResourceHttpRequestHandler]
1179
1180 All these logs are part of spring boot autoconfiguration.

1181 What does auto configuration works, where is it implementation:
1182 It is implemented in spring-boot-autoconfigure.jar

1183
1184 To get more details -
1185 - Turn on Debug logging logging.level.org.springframework: DEBUG - in
1186 your application.properties file
1187 - Use Spring Boot Actuator

1188
1189 35. What is an embedded server? Why is it important?
1190 What is the default embedded server with Spring Boot?
1191 What are the other embedded servers supported by Spring Boot?

1192
1193 We are moving towards microservices and we are developing lot of small applications. So to deploy these small applications on server we would like to have as less pre-requisite as possible.

1194
1195 Embedded Server:
1196 - Server is embedded as part of the deployable - jar or application. We can directly run this jar.
1197 - Removes the need to have the server pre-installed on the deployment environment.
1198 - Default is Tomcat.
1199 - Spring Boot also supports Jetty and Undertow.

1200
1201 Switching to Jetty:

1202 <dependency>
1203 <groupId>org.springframework.boot</groupId>
1204 <artifactId>spring-boot-starter-web</artifactId>
1205 <exclusions>
1206 <exclusion>
1207 <groupId>org.springframework.boot</groupId>
1208 <artifactId>spring-boot-starter-tomcat</artifactId>
1209 </exclusion>
1210 </exclusions>
1211 </dependency>
1212 <dependency>
1213 <groupId>org.springframework.boot</groupId>
1214 <artifactId>spring-boot-starter-jetty</artifactId>
1215 </dependency>

1216
1217
1218
1219 36. What are Starter Projects?
1220 Can you give examples of important starter projects?

1221
1222 Spring Boot Documentation:
1223 - Starters are a set of convenient dependency descriptors that you can include in your application. You get a one-stop-shop for all the Spring and related technology that you need, without having to hunt through sample code and copy paste loads of dependency descriptors.

1224
1225

1226 - For example, if you want to get started using Spring and JPA for database
access, just include the spring-boot-starter-data-jpa dependency in your
project, and you are good to go.

1227

1228 Starters:

- 1229 - spring-boot-starter-web-services - SOAP WebServices
- 1230 - spring-boot-starter-web - Web & RESTful applications
- 1231 - spring-boot-starter-test - Unit, Integration Testing
- 1232 - spring-boot-starter-jdbc - Traditional JDBC
- 1233 - spring-boot-starter-hateoas - HATEOAS features
- 1234 - spring-boot-starter-security - Authentication and Authorization using Spring
Security
- 1235 - spring-boot-starter-data-jpa - Spring Data JPA with Hibernate
- 1236 - spring-boot-starter-cache - Enabling Spring Framework's caching support
- 1237 - spring-boot-starter-data-rest - Expose Simple REST Services using Spring Data
REST - if we want to expose a JPA entity to outside world using RESTful web
service. It helps us to take the spring repositories and make them available as
a RESTful web service.
- 1238 - spring-boot-starter-actuator - To use advanced features like monitoring &
tracing to your application out of the box
- 1239 - spring-boot-starter-undertow, spring-boot-starter-jetty,
spring-boot-starter-tomcat - To pick your specific choice of Embedded Servlet
Container
- 1240 - spring-boot-starter-logging - For Logging using logback
- 1241 - spring-boot-starter-log4j2 - Logging using Log4j2

1242

1243

37. What is Starter Parent?

1245 What are the different things that are defined in Starter Parent?

1246 How does Spring Boot enforce common dependency management for all its Starter
projects?

1249 For any Spring boot application we have a spring-boot-starter-parent defined as a
parent pom.

1251 Starter Parent:

```
1252 <parent>
1253   <groupId>org.springframework.boot</groupId>
1254   <artifactId>spring-boot-starter-parent</artifactId>
1255   <version>2.0.0.RELEASE</version>
1256 </parent>
```

1258 If we look at the spring-boot-starter parent we can see that it has parent of it
own called spring-boot-dependencies and it defines lot of different things.

1260 Inside Starter Parent:

```
1261 <parent>
1262   <groupId>org.springframework.boot</groupId>
1263   <artifactId>spring-boot-dependencies</artifactId>
1264   <version>2.0.0.RELEASE</version>
1265   <relativePath>../../spring-boot-dependencies</relativePath>
1266 </parent>
1267
1268 <java.version>1.6</java.version>
1269 <resource.delimiter>@</resource.delimiter> <!-- delimiter that doesn't clash
1270 with Spring ${} placeholders -->
1271 <project.build.sourceEncoding>UTF-8</project.build.sourceEncoding>
1272 <project.reporting.outputEncoding>UTF-8</project.reporting.outputEncoding>
1273 <maven.compiler.source>${java.version}</maven.compiler.source>
1274 <maven.compiler.target>${java.version}</maven.compiler.target>
```

1277 Inside Spring Boot Dependencies:

```
1278 <ehcache3.version>3.1.1</ehcache3.version>
1279 ...
1281 <h2.version>1.4.192</h2.version>
```

```

1282     <hamcrest.version>1.3</hamcrest.version>
1283     <hazelcast.version>3.6.4</hazelcast.version>
1284     <hibernate.version>5.0.9.Final</hibernate.version>
1285     <hibernate-validator.version>5.2.4.Final</hibernate-validator.version>
1286     <jackson.version>2.8.1</jackson.version>
1287     ....
1288     <jersey.version>2.23.1</jersey.version>
1289     <spring-security.version>4.1.1.RELEASE</spring-security.version>
1290     <tomcat.version>8.5.4</tomcat.version>
1291     <xml-apis.version>1.4.01</xml-apis.version>
1292

```

In spring-boot-dependencies all the version for dependencies are defined. So when we are using spring boot we don't have to define version of any dependencies because all the version are defined in spring-boot-dependencies.

One of the problems with just spring people use to face was, what version of dependency(hibernate, jackson, etc) will play very well with the spring version I am using. We need compatible version or else there might be conflicts. This is what spring boot eliminates by specifying all dependencies versions. There versions for more than 250 jars defined.

So just need to specify the dependencies without version, based on the current spring version the spring boot will download the appropriate version. All these things we get with spring-boot starter parent.

38. What is Spring Initializr?

Spring Initializr <http://start.spring.io/> is great tool to bootstrap your Spring Boot projects.

39. What is application.properties?

What are some of the important things that can be customized in application.properties?

application.properties is used to configure your Spring Boot Application

Example Configuration:

```

1311     logging.file=
1312     logging.level.*=
1313     spring.autoconfigure.exclude=
1314     spring.profiles.active=
1315     server.error.path=/error
1316     server.port=8080
1317     spring.http.converters.preferred-json-mapper=jackson
1318
1319     spring.jackson.serialization.write-dates-as-timestamps=false           //don't
1320     serialize dates as timestamp
1321
1322     management.security.enabled=false           //when we use actuator this is enabled
1323     by default.
1324     security.basic.enabled=true
1325     security.user.name=username
1326     security.user.password=password
1327
1328     spring.jpa.show-sql=true
1329     spring.h2.console.enabled=true
1330

```

<https://docs.spring.io/spring-boot/docs/1.1.6.RELEASE/reference/html/common-application-properties.html>

<https://docs.spring.io/spring-boot/docs/1.4.x/reference/html/common-application-properties.html>

40. How do you externalize configuration using Spring Boot?

How can you add custom application properties using Spring Boot?

```

1336 What is @ConfigurationProperties?
1337
1338
1339 application.properties is the way to externalize configuration.
1340
1341 .....
1342
1343 yaml(Yet Another Mark-up Language) syntax -
1344
1345 logging:
1346     level:
1347         org.springframework: DEBUG
1348 app:
1349     name: In28Minutes
1350     description: ${app.name} is your first Spring Boot application
1351
1352 .....
1353
1354
1355 import org.springframework.boot.context.properties.ConfigurationProperties;
1356
1357 @Component
1358 @ConfigurationProperties("basic")
1359 public class BasicConfiguration {
1360     private boolean value;
1361     private String message;
1362     private int number;
1363
1364     .....
1365
1366
1367 @Autowired
1368 private BasicConfiguration configuration;
1369
1370 @RequestMapping("/dynamic-configuration")
1371 public Map dynamicConfiguration() {
1372     // Not the best practice to use a map to store differnt types!
1373     Map map = new HashMap();
1374     map.put("message", configuration.getMessage());
1375     map.put("number", configuration.getNumber());
1376     map.put("key", configuration.isValue());
1377     return map;
1378 }
1379
1380 .....
1381
1382
1383 application.properties:
1384
1385     basic.value= true
1386     basic.message= Dynamic Message
1387     basic.number= 100
1388
1389
1390 application.yaml:
1391
1392     basic:
1393         value: true
1394         message: Dynamic Message YAML
1395         number: 100
1396
1397
1398 Advantage:
1399
1400     Type Safety
1401
1402     *****
1403     APPLICATION FAILED TO START
1404     *****

```

Description:

Binding to target
com.in28minutes.springboot.configuration.BasicConfiguration@391b8545
failed:

Property: basic.number

Value: ABC

Reason: Failed to convert property value of type [java.lang.String]
to required type [int] for property 'number'; nested exception is
org.springframework.core.convert.converter.ConverterNotFoundException:
No converter found capable of converting from
type [java.lang.String] to type [int]

Action:

Update your application's configuration

Good Practice:

Design all your application configuration using ConfigurationProperties

41. What is a profile?

How do you define beans for a specific profile?

How do you create application configuration for a specific profile?

How do you have different configuration for different environments?

Profile:

```
application-dev.properties
application-qa.properties
application-stage.properties
application-prod.properties
application.properties           //define all common properties here.
```

Profile:

Based on the active profile, appropriate configuration is picked up.
Used to Configure Resources - Databases, Queues, External Services

Setting a profile:

- Using -Dspring.profiles.active=prod in VM Arguments
- OR
- In application.properties, spring.profiles.active=prod

Profiles in code: @Profile("dev") on a bean

```
@Profile("dev")
@Bean
public String devBean() {
    return "I will be available in profile dev";
}

@Profile("prod")
@Bean
public String prodBean() {
    return "I will be available in profile prod";
}
```

42. What is Spring Boot Actuator?

How do you monitor web services using Spring Boot Actuator?

How do you find more information about your application environment using Spring Boot?

Spring Boot Actuator: Is a application which we can use to monitor our application.
We just need to add its dependency, thats it. It exposes a lot of URIs / services -

```

1472 Monitoring
1473     /env, /metrics, /trace, /dump
1474     /beans, / autoconfig, /configprops, /mappings
1475
1476 <dependency>
1477     <groupId>org.springframework.boot</groupId>
1478     <artifactId>spring-boot-starter-actuator</artifactId>
1479 </dependency>
1480
1481 Actuator provides lot of monitoring facilities around your services.
1482
1483 We also would like to see the services which are provided by actuator in a browser.
1484 For this we add below dependency -
1485
1486 <dependency>
1487     <groupId>org.springframework.data</groupId>
1488     <artifactId>spring-data-rest-hal-browser</artifactId>
1489 </dependency>
1490
1491 HAL is a specific format - Hypertext Application Language. HAL is a simple format
1492 that gives a consistent and easy way to hyperlink between resources in your API.
1493 spring-boot-starter-actuator apis are in HAL format. So what HAL does it it looks
1494 at apis, identifies the links and show them on screen.
1495
1496 Actuator URLs are also changing a lot along with spring-boot versions -
1497     localhost:8080/actuator
1498     localhost:8080/application
1499
1500 To enable few things we need to add a property:
1501     management.endpoint.web.exposure.include=* //we are enabling a web
1502     exposure here. Enabling everything may impact the performance, so it better to
1503     enable only those that we need.
1504
1505 Now after localhost:8080/actuator or localhost:8080/application we will get lot
1506 more links.
1507
1508 If we just type localhost:8080 we will go to HAL browser. And after entering
1509 /actuator in Explorer input box we will get all links
1510
1511 httptrace - will show all the requests that are comming in, response, time taken,
1512 etc. of all previous request also. This will impact performance so can't use in
1513 production enviornment.
1514
1515 43. What is a CommandLineRunner?
1516
1517 CommandLineRunner:
1518
1519 Spring Documentation - interface used to indicate that a bean should run when it is
1520 contained within a SpringApplication
1521
1522 public interface CommandLineRunner {
1523     void run(String... args) throws Exception;
1524 }
1525
1526 Once spring application context has launched up then, the code in run() method will
1527 be executed.
1528 Can be used if we want to do something after application startup, like populate the
1529 data, configure somthing, etc.
1530
1531 44. What is Spring JDBC? How is different from JDBC?
1532 What is a JdbcTemplate?
1533 What is a RowMapper?
1534
1535 JDBC - Update Todo:
1536
1537     Connection connection = datasource.getConnection();

```

```

1529
1530     PreparedStatement st = connection.prepareStatement("Update todo set user=?,
1531     desc=?, target_date=?, is_done=? where id=?");
1532
1533     st.setString(1, todo.getUser());
1534     st.setString(2, todo.getDesc());
1535     st.setTimestamp(3, new Timestamp(todo.getTargetDate().getTime()));
1536     st.setBoolean(4, todo.isDone());
1537     st.setInt(5, todo.getId());
1538
1539     st.execute();
1540     st.close();
1541     connection.close();
1542
1543     ..... lot of code to do simple update.
1544
1545 Spring JDBC:
1546
1547     jdbcTemplate.update("Update todo set user=?, desc=?, target_date=?, is_done=?
1548     where id=?",
1549         todo.getUser(), todo.getDesc(), new
1550         Timestamp(todo.getTargetDate().getTime()), todo.isDone(),
1551         todo.getId());
1552
1553     jdbcTemplate.update("delete from todo where id=?", id);
1554
1555     jdbcTemplate has lot of othe ruseful methods. It reduces the number of lines of
1556     code, complexity of JDBC. No need to handle the exception with try-catch. There
1557     is no need to manage resource connections (st.close(), connection.close(), etc).
1558
1559 Spring JDBC - RowMapper: helps in mapping a bean with a table.
1560
1561     new BeanPropertyRowMapper(Todo.class)          //if your bean name or name of
1562     properties in it exactly matches the column names, then we can use
1563     BeanPropertyRowMapper directly, or else we will have to do explicit mapping
1564     like below using mapRow()
1565
1566     .....
1567
1568     class TodoMapper implements RowMapper<Todo> {
1569
1570         @Override
1571         public Todo mapRow(ResultSet rs, int rowNum) throws SQLException {
1572
1573             Todo todo = new Todo();
1574
1575             todo.setId(rs.getInt("id"));
1576             todo.setUser(rs.getString("user"));
1577             todo.setDesc(rs.getString("desc"));
1578             todo.setTargetDate(rs.getTimestamp("target_date"));
1579             todo.setDone(rs.getBoolean("is_done"));
1580             return todo;
1581         }
1582     }
1583
1584     Once we create a RowMapper like above, we can reuse it anywhere like below code
1585     -
1586
1587     return jdbcTemplate.query(
1588         "SELECT * FROM TODO where user = ?",
1589         new Object[] { user }, new TodoMapper());
1590
1591     .....
1592
1593     return jdbcTemplate.queryForObject(
1594         "SELECT * FROM TODO where id=?",

```

```
1588         new Object[] { id }, new TodoMapper())
```

```
1589
1590
```

```
1591 45. What is JPA?
```

```
1592     What is Hibernate?
```

```
1593     How do you define an entity in JPA?
```

```
1594     What is an Entity Manager?
```

```
1595     What is a Persistence Context?
```

```
1596
1597
```

```
1598     In above examples we were writting lot of queries. Some queries can get complex and
    big and generally these are written by java developers who might not be expert in
    database.
```

```
1599     JPA defines a mapping from our java object to a row in a table. We just need to
    define the proper mapping and JPA implementation(hibernate) will take care of
    generating the queries for us.
```

```
1600
1601
```

```
1602     Hibernate - JPA implementation. JPA is specification or standard or interface.
```

```
1603
1604
```

```
1605     @Entity
```

```
1606     @Table(name = "Todo")
```

```
1607     public class Todo {
```

```
1608
1609
```

```
1610         @Id
1611         @GeneratedValue(strategy = GenerationType.IDENTITY)
```

```
1612         private int id;
```

```
1613
1614
```

```
1615         private String user;
```

```
1616         private String desc;
```

```
1617
1618
```

```
1619         private Date targetDate;
```

```
1620         private boolean isDone;
```

```
1621
1622
```

```
1623     .....
1624     public class TodoJPAService implements TodoDataService {
```

```
1625         @PersistenceContext
```

```
1626         private EntityManager entityManager;
```

```
1627
1628
```

```
1629         @Override
```

```
1630         public void updateTodo(Todo todo) {
```

```
1631             entityManager.merge(todo);
```

```
1632         }
1633     .....
1634
```

```
1635     Once we have defined all the entities, PersistenceContext is the one which is used
    to manage all those entities. So whatever changes we make has to go through
    PersistenceContext.
```

```
1636     We can access the PersistenceContext using EntityManager.
```

```
1637
1638
```

```
1639 46. How do you map relationships in JPA?
```

```
1640     What are the different types of relationships in JPA?
```

```
1641     How do you define One to One Mapping in JPA?
```

```
1642     How do you define One to Many Mapping in JPA?
```

```
1643     How do you define Many to Many Mapping in JPA?
```

```
1644
1645
```

```
1646     One to One Relationship:
```

```
1647         @Entity
```

```
1648         public class Passport {
```

```
1649
1650     ....
```

```
1651
1652 //we are doing mappedBy="passport" because we want passport_id column in
Student table. If we remove it we will have both, student_id in Passport
table and also passport_id in Student table and this is not what we want, in
one to one we would want one of the table to own the relationship.
```

```
1653
1654 @OneToOne(fetch = FetchType.LAZY, mappedBy = "passport")
1655 private Student student;
1656
1657 .....
1658
1659 @Entity
1660 @Table(name = "Student")
1661 public class Student {
1662
1663     @OneToOne
1664     private Passport passport;
1665
1666     .....
1667
```

One to Many Relationship:

```
1669
1670 @Entity
1671 public class Project {
1672     @OneToMany(mappedBy = "project")
1673     private List<Task> tasks;
1674
1675     .....
1676
1677 @Entity
1678 public class Task {
1679     @ManyToOne
1680     @JoinColumn(name="PROJECT_ID")
1681     private Project project;
1682
1683     .....
1684
```

Many to Many Relationship: Third table is created.

```
1685
1686 @Entity
1687 public class Project {
1688
1689     @ManyToMany
1690     // @JoinTable(name="STUDENT_PROJ",
1691     // joinColumns=@JoinColumn(name="STUDENT_ID"),
1692     // inverseJoinColumns=@JoinColumn(name="PROJECT_ID"))
1693     private List<Student> students;
1694
1695     .....
1696
1697 public class Student {
1698     @ManyToMany(mappedBy = "students")
1699     private List<Project> projects;
1700
1701
1702
```

47. How do you define a datasource in a Spring Context?

What is the use of persistence.xml

How do you configure Entity Manager Factory and Transaction Manager?

How do you define transaction management for Spring - Hibernate integration?

Defining a Data Source:

```
1710
1711 #HSQL in-memory db
1712 db.driver=org.hsqldb.jdbcDriver
1713 db.url=jdbc:hsqldb:mem:firstdb
1714 db.username=sa
1715 db.password=
1716
```

```

1717 <bean id="dataSource" class="com.mchange.v2.c3p0.ComboPooledDataSource"
1718     destroy-method="close">
1719     <property name="driverClass" value="${db.driver}" />
1719     <property name="jdbcUrl" value="${db.url}" />
1720     <property name="user" value="${db.username}" />
1721     <property name="password" value="${db.password}" />
1722 </bean>
1723
1724

```

Configuring Hibernate: src\main\resources\config\hibernate.properties

```

1726 hibernate.dialect=org.hibernate.dialect.HSQLDialect
1727 hibernate.show_sql=false
1728 hibernate.format_sql=false
1729 hibernate.use_sql_comments=true
1730
1731
1732

```

persistence.xml: src\main\resources\META-INF\persistence.xml - Used to configure our persistence unit. JPA mandates that we will need persistence.xml

```

1734 <?xml version="1.0" encoding="UTF-8"?>
1735
1736 <persistence xmlns="http://java.sun.com/xml/ns/persistence"
1737     version="2.0">
1738     <persistence-unit name="hsqldb" transaction-type="RESOURCE_LOCAL">
1739         <provider>org.hibernate.jpa.HibernatePersistenceProvider</provider>
1740         <properties>
1741             <property name="hibernate.dialect"
1742                 value="org.hibernate.dialect.HSQLDialect" />
1743             <property name="hibernate.connection.url" value="jdbc:hsqldb:mem:firstdb"
1744                 />
1745             <property name="hibernate.connection.driver_class"
1746                 value="org.hsqldb.jdbcDriver" />
1747             <property name="hibernate.connection.username" value="sa" />
1748             <property name="hibernate.connection.password" value="" />
1749         </properties>
1750     </persistence-unit>
1751 </persistence>

```

Configure Entity Manager Factory and Transaction Manager:

```

1752 <bean
1753     class="org.springframework.orm.jpa.LocalContainerEntityManagerFactoryBean"
1754     id="entityManagerFactory">
1755     <property name="persistenceUnitName" value="hsqldb" />
1756     <property name="dataSource" ref="dataSource" />
1757 </bean>
1758
1759 <bean id="transactionManager"
1760     class="org.springframework.orm.jpa.JpaTransactionManager">
1761     <property name="entityManagerFactory" ref="entityManagerFactory" />
1762     <property name="dataSource" ref="dataSource" />
1763 </bean>
1764
1765 <tx:annotation-driven transaction-manager="transactionManager"/>
1766

```

Making Service Transactional:

```

1767 @Service
1768 public class StudentService {
1769
1770     @Autowired
1771     StudentRepository service;
1772
1773     @Transactional
1774     public Student insertStudent(Student student) {
1775         return service.insertStudent(student);
1776     }
1777

```

```

1778         }
1779
1780         .....
1781
1782         @Service
1783         @Transactional
1784         public class StudentService {
1785
1786             @Autowired
1787             StudentRepository service;
1788
1789             .....
1790
1791

```

48. What is Spring Data?

What is the need for Spring Data?
 What is Spring Data JPA?

Duplication in JPA Repositories: Passport Repository

```

1799     @PersistenceContext
1800     private EntityManager entityManager;
1801
1802     public Passport getPassport(final long id) {
1803         Passport passport = entityManager.find(Passport.class, id);
1804         return passport;
1805     }
1806
1807     public Passport createPassport(Passport passport) {
1808         return entityManager.merge(passport);
1809     }
1810

```

Duplication in JPA Repositories: Student Repository

```

1814     @PersistenceContext
1815     private EntityManager entityManager;
1816
1817     public Student retrieveStudent(final long id) {
1818         return entityManager.find(Student.class, id);
1819     }
1820
1821     public Student createStudent(Student student) {
1822         return entityManager.merge(student);
1823     }
1824

```

So there is lot of duplication in the Passport repository and in Student repository

Explosion of Data Stores:

Variety of Big Data Stores

Spring Data:

Common Abstractions to store and retrieve data from data stores
 Independent of type of data store - it doesn't matter if we are talking to
 relation database, or big data store

Spring Data JPA:

Extends Spring Data for connecting to JPA

Using Spring Data JPA:

```

1839     public interface StudentRepository extends CrudRepository<Student, Long> {
1840     }
1841
1842     public interface PassportRepository extends CrudRepository<Passport, Long> {
1843     }
1844

```

- 1846 49. What is a CrudRepository?
1847 What is a PagingAndSortingRepository?
1848
1849

1850 CrudRepository:

```
1851  
1852     public interface CrudRepository<T, ID> extends Repository<T, ID> {  
1853         <S extends T> S save(S entity);  
1854         Optional<T> findById(ID id);  
1855         boolean existsById(ID id);  
1856         Iterable<T> findAll();  
1857         void deleteById(ID id);  
1858         long count();  
1859         //Other Methods  
1860     }
```

1861
1862 PagingAndSortingRepository: Pagination and Sorting:

```
1863  
1864     public interface PagingAndSortingRepository<T, ID> extends CrudRepository<T,  
1865     ID> {  
1866         Iterable<T> findAll(Sort sort);  
1867         Page<T> findAll(Pageable pageable);  
1868     }
```

1869 Using PagingAndSortingRepository:

```
1870  
1871     Sort sort = new Sort(Sort.Direction.DESC, "field_name");  
1872     passportRepository.findAll(sort);  
1873     //Page Size - 10  
1874     PageRequest pageable = new PageRequest(0,10);  
1875     Page<Passport> page = passportRepository.findAll(pageable);  
1876     System.out.println(userPage.getTotalPages());  
1877     System.out.println(userPage.nextPageable());  
1878  
1879
```

- 1880 50. How does Spring Framework Make Unit Testing Easy?
1881 What is Mockito?
1882 What is your favorite mocking framework?
1883 How do you do mock data with Mockito?
1884 What are the different mocking annotations that you worked with?
1885
1886

```
1887     public class SomeBusinessImpl {  
1888  
1889         private DataService dataService;  
1890  
1891         //Constructor - public SomeBusinessImpl(DataService dataService)  
1892  
1893         int findTheGreatestFromAllData() {  
1894  
1895             int[] data = dataService.retrieveAllData();  
1896             int greatest = Integer.MIN_VALUE;  
1897  
1898             for (int value : data) {  
1899                 if (value > greatest) {  
1900                     greatest = value;  
1901                 }  
1902             }  
1903             return greatest;  
1904         }  
1905  
1906     }
```

1907
1908
1909 Basic Mocking:

```
1910  
1911     @Test  
1912     public void testFindTheGreatestFromAllData() {  
1913
```

```

1914         //we don't want database dependency, because if its down unit test will fail.
1915         If we talk with real object and communicate with db then it becomes a
1916         integration test. It is no longer a Unit test.
1917         DataService dataServiceMock = mock(DataService.class);
1918
1919         when(dataServiceMock.retrieveAllData())
1920             .thenReturn(new int[] { 24, 15, 3 });
1921
1922         SomeBusinessImpl businessImpl = new SomeBusinessImpl(dataServiceMock);
1923
1924         int result = businessImpl.findTheGreatestFromAllData();
1925
1926         assertEquals(24, result);
1927     }

```

Using Annotations:

```

1929
1930     @RunWith(MockitoJUnitRunner.class)
1931     public class SomeBusinessMockAnnotationsTest {
1932
1933         @Mock
1934         DataService dataServiceMock;
1935
1936         @InjectMocks
1937         SomeBusinessImpl businessImpl;
1938
1939         @Test
1940         public void testFindTheGreatestFromAllData() {
1941             when(dataServiceMock.retrieveAllData())
1942                 .thenReturn(new int[] { 24, 15, 3 });
1943             assertEquals(24, businessImpl.findTheGreatestFromAllData());
1944         }
1945
1946         .....

```

MockitoJUnitRunner will create a mock and will inject it into the SomeBusinessImpl.

51. What is MockMvc?
- What is @WebMvcTest?
- What is @MockBean?
- How do you write a unit test with MockMVC?
- What is JSONAssert?

Mock MVC Test with Spring Boot:

```

1958
1959
1960     public Question retrieveDetailsForQuestion(@PathVariable String surveyId,
1961         @PathVariable String questionId) {
1962         return surveyService.retrieveQuestion(surveyId, questionId);
1963     }
1964     .....
1965
1966     @RunWith(SpringRunner.class)
1967     @WebMvcTest(value = SurveyController.class, secure = false)
1968     public class SurveyControllerTest {
1969
1970         @Autowired
1971         private MockMvc mockMvc;
1972
1973         @MockBean
1974         private SurveyService surveyService;
1975
1976         @Test
1977         public void retrieveDetailsForQuestion() throws Exception {
1978             Question mockQuestion = new Question("Question1", "Largest Country in the
1979                 World", "Russia", Arrays.asList("India", "Russia", "United States", "China"));

```

```

1979 Mockito.when(
1980     surveyService.retrieveQuestion(Mockito.anyString(),
1981     Mockito.anyString())) .thenReturn(mockQuestion);
1982
1983 RequestBuilder requestBuilder =
1984 MockMvcRequestBuilders.get("/surveys/Survey1/questions/Question1").accept(Media
1985 Type.APPLICATION_JSON);
1986
1987 MvcResult result = mockMvc.perform(requestBuilder)
1988     .andReturn();
1989
1990 String expected = "{id:Question1,description:Largest Country in the
1991 World,correctAnswer:Russia}";
1992
1993 JSONAssert.assertEquals(expected, result.getResponse().getContentAsString(),
1994 false);
1995
1996 // Assert
1997 }
1998
1999
2000

```

52. How do you write an integration test with Spring Boot?

What is @SpringBootTest?
 What is @LocalServerPort?
 What is TestRestTemplate?

In integration test we launch entire application as it is and then check what result comes back.

@SpringBootTest - launches up the real server

@LocalServerPort - helps to get the port on which application is running

@TestRestTemplate - To execute the request.

Integration Test with Spring Boot:

```

2006 @RunWith(SpringRunner.class)
2007 @SpringBootTest(classes = Application.class, webEnvironment =
2008 SpringBootTest.WebEnvironment.RANDOM_PORT)    //we are specifying the random
2009 port to be used. We can also specify a port number.
2010 public class SurveyControllerIT {
2011
2012     @LocalServerPort
2013     private int port;                //whatever the port is used will be autowired
2014                                     here. We will need it later to fire request.
2015 }
2016 .....
2017
2018 @Test
2019 public void testRetrieveSurveyQuestion() {
2020
2021     String url = "http://localhost:" + port + "/surveys/Survey1/questions/Question1";
2022
2023     HttpHeaders headers = new HttpHeaders();
2024     headers.setAccept(Arrays.asList(MediaType.APPLICATION_JSON));
2025
2026     HttpEntity<String> entity = new HttpEntity<String>(null, headers);    //when
2027     we want to send a request with accept headers we need HttpEntity. HttpEntity
2028     allows us to create a request with headers.
2029
2030     TestRestTemplate restTemplate = new TestRestTemplate();
2031     ResponseEntity<String> response = restTemplate.exchange(url, HttpMethod.GET,
2032     entity, String.class);
2033
2034     String expected = "{id:Question1,description:Largest Country in the
2035     World,correctAnswer:Russia}";
2036
2037     JSONAssert.assertEquals(expected, response.getBody(), false);
2038 }

```

2035
2036
2037 53. What are cross cutting concerns?
2038 How do you implement cross cutting concerns in a web application?
2039 If you would want to log every request to a web application, what are the options
you can think of?
2040 If you would want to track performance of every request, what options can you think
of?
2041
2042
2043 Check the diagram.
2044
2045 When we talk about a web application there are multiple layer, like web, business,
data, integration, etc. Each of these layer has its own purpose and specialization.
But some these are commons amongs all these layer, like log, security, etc. These
are concerns of all the layers in the application and they are called cross-cutting
concerns.
2046 Typically all these cross cutting concerns are implemented by Aspect Oriented
Programming (AOP).
2047
2048 Example - If we want to log every request that is coming to the application - One
of the option which Java EE provides is to configure a filter and then add methods
to log the request and log the response back. Other way is AOP, saying we would
want to configure all the calls to a particular controller.
2049
2050
2051 We have separete notes on AOP. Check.
2052
2053
2054 54. What is an Aspect and Pointcut in AOP?
2055 What are the different types of AOP advices?
2056 What is weaving?
2057
2058
2059 @Component
2060 class HiByeService {
2061 public void sayHi(String name) {
2062 System.out.println("Hi " + name);
2063 }
2064
2065 public void sayBye() {
2066 System.out.println("Bye");
2067 }
2068
2069 public String returnSomething() {
2070 return "Hi Bye";
2071 }
2072 }
2073
2074
2075
2076 @Aspect
2077 @Component
2078 class MyAspect {
2079 @Before("execution(* HiByeService.*(..))") //any method on
HiByeService.* (..) -> for any arguments
2080 public void before(JoinPoint joinPoint) {
2081 System.out.print("Before ");
2082 System.out.print(joinPoint.getSignature().getName());
2083 System.out.println(Arrays.toString(joinPoint.getArgs()));
2084 }
2085
2086 @AfterReturning(pointcut = "execution(* HiByeService.*(..))", returning = "result")
2087 public void after(JoinPoint joinPoint, Object result)
{
//result or return value will available to us in
Object result
2088 System.out.print("After ");
2089 System.out.print(joinPoint.getSignature().getName());
2090 System.out.println(" result is " + result);

```

2091     }
2092 }
2093
2094 .....
2095
2096 @Around(value = "execution(* HiByeService.*(..))")
2097 public void around(ProceedingJoinPoint joinPoint) throws Throwable {
2098     long startTime = new Date().getTime();
2099     Object result = joinPoint.proceed();
2100     long endTime = new Date().getTime();
2101     System.out.print("Execution Time - " + (endTime - startTime));
2102     //calculating the entire execution time of method.
2103 }
2104 .....

```

If we have a bean and if property value of bean is changed, even such kind of things we can find out using AspectJ.

56.

AOP concepts:

- Joinpoint -> is a specific result of one execution. If a method is called 100 times, we will have 100 different JoinPoints.
- Advice -> what you want to do, which method you want to execute. Above all AOP methods and code is advice, Around advice, Before advice, etc.
- Pointcut -> helps to identify what kind of methods we want to intercept. What exactly we want to intercept.
- Aspect -> Combination of Advice and Pointcut. Advice + Pointcut
- Weaving -> is just a process of making sure that these methods are getting called at the right instance or right time.
- Weaver -> is AOP framework like Spring AOP or AspectJ

With Spring AOP we can do basic weaving while with AspectJ we can do advanced weaving.

With Spring AOP we can only intercept method calls, with AspectJ we can do lot more.

Advice Types:

- Before advice
- After returning advice
- After throwing advice
- After (finally) advice - Always executed - similar to finally
- Around advice - Most powerful - Performance Logging

AspectJ vs Spring AOP:

- AspectJ is a full fledged AOP framework
- Advise objects not managed by the Spring container
- Advise join points other than simple method executions (for example, field get or set join points)

57. What is a Web Service?

Check diagram.

3 Keys:

- Designed for machine-to-machine (or application-to-application) interaction
- Should be interoperable - Not platform dependent - we can do this by making our request and response platform independent.
- Should allow communication over a network

58. What is SOAP Web Service?

What is SOAP?

What is a SOAP Envelope?

2151 What is SOAP Header and SOAP Body?

2152

2153 This is Not SOAP Web Service - check diagram -
C:\Users\inarajp\Desktop\temp\spring-interview-guide-master\spring-interview-guide-master\1.presentation\images\Web_Service_Basic_Interaction_SOAP

2154

2155 This is SOAP Web Service - check diagram -
C:\Users\inarajp\Desktop\temp\spring-interview-guide-master\spring-interview-guide-master\1.presentation\images\Web_Service_Basic_Interaction_SOAP_2

2156

2157 check diagram -
C:\Users\inarajp\Desktop\temp\spring-interview-guide-master\spring-interview-guide-master\1.presentation\images\Web_Service_SOAP-Envelope.svg

2158

2159 SOAP (Simple Object Access Protocol):

2160 Format

2161 - SOAP XML Request

2162 - SOAP XML Response

2163 Transport

2164 - SOAP over MQ

2165 - SOAP over HTTP

2166 Service Definition

2167 - WSDL

2168

2169 SOAP-ENV: Envelope

2170

2171 SOAP-ENV: Header - Contains meta information, authentication information, etc.

2172

2173 SOAP-ENV: Body - Has the actual content

2174

2175

2176 59. Can you give an example of SOAP Request and SOAP Response?

2177 What is a SOAP Header? What kind of information is sent in a SOAP Header?

2178 Can you give an example of a SOAP Header with Authentication information?

2179

2180

2181 SOAP Request:

2182

2183 <SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">

2184 <SOAP-ENV:Header/>

2185 <SOAP-ENV:Body>

2186 <ns2:GetCourseDetailsRequest xmlns:ns2="http://in28minutes.com/courses">

2187 <ns2:course>

2188 <ns2:id>1</ns2:id>

2189 </ns2:course>

2190 </ns2:GetCourseDetailsRequest>

2191 </SOAP-ENV:Body>

2192 </SOAP-ENV:Envelope>

2193

2194

2195 SOAP Response:

2196

2197 <SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">

2198 <SOAP-ENV:Header/>

2199 <SOAP-ENV:Body>

2200 <ns2:getCourseDetailsResponse xmlns:ns2="http://in28minutes.com/courses">

2201 <ns2:course>

2202 <ns2:id>1</ns2:id>

2203 <ns2:name>Spring</ns2:name>

2204 <ns2:description>10 Steps</ns2:description>

2205 </ns2:course>

2206 </ns2:getCourseDetailsResponse>

2207 </SOAP-ENV:Body>

2208 </SOAP-ENV:Envelope>

2209

2210 SOAP Header:

2211

2212 <Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">

2213 <Header>

```

2214         <wsse:Security
xmlns:wsse="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurit
y-seext-1.0.xsd" mustUnderstand="1">
2215             <wsse:UsernameToken>
2216                 <wsse:Username>user</wsse:Username>
2217                 <wsse:Password>password</wsse:Password>
2218             </wsse:UsernameToken>
2219         </wsse:Security>
2220     </Header>
2221     <Body>
2222         <GetCourseDetailsRequest xmlns="http://in28minutes.com/courses">
2223             <id>1</id>
2224         </GetCourseDetailsRequest>
2225     </Body>
2226 </Envelope>

```

wsse is one of the implementation of the standards for SOAP security

60. What is WSDL (Web Service Definition Language)?
What are the different parts of a WSDL?

WSDL - Web Service Definition Language

If we provide WSDL to any of the client, they will know every detail about how to call a web-service (odb-adapter)

Diagram -

C:\Users\inarajp\Desktop\temp\spring-interview-guide-master\spring-interview-guide-master\1.presentation\images\Web_Services_WSDL_HighLevel

All Operations - Which are webservice(methods), what is input to it

Endpoint

Request Structure

Response Structure

We can also import XSD, XSDs can define request and response structures.

C:\Users\inarajp\Desktop\temp\spring-interview-guide-master\spring-interview-guide-master\1.presentation\images\Web_Services_WSDL_LowLevel

definitions

- types(defines what are different xml structure which we are going to use)
 - element
 - complexType

- message (defines different requests and responses for different operations. The only thing that can be used as request or response elements are the one that are mapped as a message. We can't directly use types as request or response element, it has to be a message)

- portType (defines different operations, maps request message and response message to a operation. Its like an interface - this webservice offers these services)

- operation
 - input
 - output

- binding (defines the implementation, how do you really call these services or operations defined in portType. Here we define style (document - to indicate that we are exchanging the complete XML request and response, Other option - RPC(Remote procedure call - like calling a procedure defined somewhere else)) and transport (http - web/internet, other option is MQ))

- operation
 - input
 - output

2267 - service (what is the location, how client will use it. Maps it to
2268 endpoint, what is the url to call web service)
2269 - port
2270

2271 61. What is Contract First Approach?

2272 What is an XSD?

2273 Can you give an example of an XSD?

2274
2275

2276 Contract: Service Definition specifying

- 2277 - Format of Request
 - 2278 - Format of Response
 - 2279 - Request/Response Structure
 - 2280 - Transport used
 - 2281 - Endpoint details
- 2282

2283 Contract First - We define a contract first!

2284

2285 With Spring Web Services, we define an XSD first

2286

2287 XSD:

2288 XML Specification Document!
2289 How does a valid XML Look like?

2290

2291 Request XML:

```
2292       <GetCourseDetailsRequest xmlns="http://in28minutes.com/courses">  
2293           <id>1</id>  
2294       </GetCourseDetailsRequest>
```

2295

2296 XSD:

```
2297       <xs:element name="GetCourseDetailsRequest">  
2298           <xs:complexType>  
2299               <xs:sequence>  
2300                   <xs:element name="id" type="xs:int" />  
2301               </xs:sequence>  
2302           </xs:complexType>  
2303       </xs:element>
```

2304

2305 Response XML:

```
2306       <ns2:GetCourseDetailsResponse xmlns:ns2="http://in28minutes.com/courses">  
2307           <ns2:CourseDetails>  
2308               <ns2:id>1</ns2:id>  
2309               <ns2:name>Spring</ns2:name>  
2310               <ns2:description>10 Steps</ns2:description>  
2311           </ns2:CourseDetails>  
2312       </ns2:GetCourseDetailsResponse>
```

2313

2314

2315 XSD:

```
2316       <xs:element name="GetCourseDetailsResponse">  
2317           <xs:complexType>  
2318               <xs:sequence>  
2319                   <xs:element name="CourseDetails" type="tns:CourseDetails" />  
2320               </xs:sequence>  
2321           </xs:complexType>  
2322       </xs:element>
```

2323

2324 XSD:

```
2325       <xs:complexType name="CourseDetails">  
2326           <xs:sequence>  
2327               <xs:element name="id" type="xs:int" />  
2328               <xs:element name="name" type="xs:string" />  
2329               <xs:element name="description" type="xs:string" />  
2330           </xs:sequence>  
2331       </xs:complexType>
```

2332

2333 Once XSDs are created, Spring web services provides us a feature where in we can generate WSDL out of our XSDs.

2334
2335
2336 62. What is JAXB?

2337 How do you configure a JAXB Plugin?

2338
2339 JAXB (Java API for XML Binding)

2340
2341 Convert from Java to SOAP XML

2342
2343 Request or input will be XML and Response or output will be also a XML.

2344
2345 So JAXB will convert XML(Request) to java objects and java objects to XML(Response).

2346
2347 JAXB defines a specification about how to do this kind of conversion.

2348
2349 JAXB Plugin:

```
2350  
2351 <plugin>  
2352   <groupId>org.codehaus.mojo</groupId>  
2353   <artifactId>jaxb2-maven-plugin</artifactId>  
2354   <version>1.6</version>  
2355   <executions>  
2356     <execution>  
2357       <id>xjc</id>  
2358       <goals>  
2359         <goal>xjc</goal>  
2360       </goals>  
2361     </execution>  
2362   </executions>  
2363   <configuration>  
2364     <schemaDirectory>${project.basedir}/src/main/resources</schemaDirectory>  
2365     <outputDirectory>${project.basedir}/src/main/java</outputDirectory>  
2366     <clearOutputDir>false</clearOutputDir>  
2367   </configuration>  
2368 </plugin>
```

2369
2370 JAXB plugins takes a schema directory and it generates java class from it.

2371
2372
2373 63. What is an Endpoint?

2374 Can you show an example endpoint written with Spring Web Services?

2375
2376
2377 Endpoint: Where are web services are exposed. It will accept the request, it will then call the service to execute the business logic, and it will send the response out.

```
2378  
2379 @PayloadRoot(namespace = "http://in28minutes.com/courses", localPart =  
    "GetCourseDetailsRequest")
```

```
2380 @ResponsePayload  
2381 public GetCourseDetailsResponse processCourseDetailsRequest(@RequestPayload  
    GetCourseDetailsRequest request) {
```

```
2382     Course course = service.findById(request.getId());
```

```
2383     if (course == null)  
2384       throw new CourseNotFoundException("Invalid Course Id " + request.getId());
```

```
2387     return mapCourseDetails(course);  
2388   }  
2389 }
```

2390
2391 @PayloadRoot - defines what kind of requests it can handle, we are saying that any request with namespace as ... and localPart as ... can be handled by this service. GetCourseDetailsRequest and GetCourseDetailsResponse are classes generated by JAXB. @RequestPayload - will map the details from request to the GetCourseDetailsRequest parameter object. XML bound to java object.
2392
2393 @ResponsePayload - will map the object to response. Java object converted to XML response.
2394
2395

```

2396
2397 64. What is a MessageDispatcherServlet?
2398 How do you configure a MessageDispatcherServlet?
2399
2400 MessageDispatcherServlet: Now know that in spring mvc DispatcherServlet acts as a
front controller, all the request first comes to DispatcherServlet and from there
it goes to respective controller. In case of spring web services
MessageDispatcherServlet does exactly the same thing. The request first goes to
MessageDispatcherServlet, it then looks at the request, looks at the namespace and
messages details and then maps it to the appropriate endpoint method and call it.

2401
2402 Configuring the MessageDispatcherServlet -
2403
2404 @Bean
2405 public ServletRegistrationBean messageDispatcherServlet(ApplicationContext context) {
2406
2407     MessageDispatcherServlet messageDispatcherServlet = new MessageDispatcherServlet();
2408     messageDispatcherServlet.setApplicationContext(context);
2409     messageDispatcherServlet.setTransformWsdlLocations(true);
2410
2411     return new ServletRegistrationBean(messageDispatcherServlet, "/ws/*");
2412 }
2413
2414 MessageDispatcherServlet is actually a servlet, so in spring if we want to
configure a servlet we would use ServletRegistrationBean.
ServletRegistrationBean accepts two things - Servlet and URI.

2415
2416
2417
2418 65. How do you generate a WSDL using Spring Web Services?
2419
2420 @Bean(name = "courses")
2421 public DefaultWsdll11Definition defaultWsdll11Definition(XsdSchema coursesSchema) {
2422
2423     DefaultWsdll11Definition definition = new DefaultWsdll11Definition();
2424     definition.setPortTypeName("CoursePort");
2425     definition.setTargetNamespace("http://in28minutes.com/courses");
2426     definition.setLocationUri("/ws");
2427     definition.setSchema(coursesSchema);
2428     return definition;
2429 }
2430
2431 @Bean
2432 public XsdSchema coursesSchema() {
2433     return new SimpleXsdSchema(new ClassPathResource("course-details.xsd"));
2434 }
2435
2436
2437 66. How do you implement error handling for SOAP Web Services?
2438 What is a SOAP Fault?
2439
2440 Whenever an error occurs we would want to give a correct error response back to the
client. And SOAP fault is an structure in which we can send error response back.

2441
2442 Endpoint:
2443
2444 @PayloadRoot(namespace = "http://in28minutes.com/courses", localPart =
"GetCourseDetailsRequest")
2445 @ResponsePayload
2446 public GetCourseDetailsResponse processCourseDetailsRequest(@RequestPayload
GetCourseDetailsRequest request) {
2447
2448     Course course = service.findById(request.getId());
2449
2450     if (course == null)
2451         throw new CourseNotFoundException("Invalid Course Id " + request.getId());
2452
2453     return mapCourseDetails(course);
2454 }
2455

```

```

2456 <SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
2457   <SOAP-ENV:Header/>
2458   <SOAP-ENV:Body>
2459     <SOAP-ENV:Fault>
2460       <faultcode>SOAP-ENV:Server</faultcode> //we
2461       can change this
2462       <faultstring xml:lang="en">Invalid Course Id 1000</faultstring>
2463     </SOAP-ENV:Fault>
2464   </SOAP-ENV:Body>
2465 </SOAP-ENV:Envelope>
2466
2467
2468 @SoapFault(
2469     faultCode = FaultCode.CUSTOM,
2470     customFaultCode = "{http://in28minutes.com/courses}001_COURSE_NOT_FOUND")
2471 public class CourseNotFoundException extends RuntimeException {
2472     //custom exception class
2473 }
2474
2475 <SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
2476   <SOAP-ENV:Header />
2477   <SOAP-ENV:Body>
2478     <SOAP-ENV:Fault>
2479       <faultcode
2480         xmlns:ns0="http://in28minutes.com/courses">ns0:001_COURSE_NOT_FOUND</faultcode>
2481       <faultstring xml:lang="en">Invalid Course Id 1234</faultstring>
2482     </SOAP-ENV:Fault>
2483   </SOAP-ENV:Body>
2484 </SOAP-ENV:Envelope>

```

We can also use FaultCode.CLIENT

67. What is REST?

REpresentational State Transfer

REST is a style of software architecture for distributed hypermedia systems.

When we are talking about SOAP web services we are focussed on the format. We are focussed on using SOAP envelop, SOAP header and SOAP body. REST only sets some architectural guidelines and thats all. It does not worry about what format of request we are sending, etc.

REST wants to make best use of HTTP. HTTP provides HTTP Methods, HTTP Status

Diagram -

Anything and everything is a resource.

Key abstraction - Resource

A resource has an URI (Uniform Resource Identifier)

/users/Ranga/todos/1

/users/Ranga/todos

/users/Ranga

We can perform operations on these resources.

Example:

Create a User - POST /users

Delete a User - DELETE /users/1

Get all Users - GET /users

Get one Users - GET /users/1

REST:

Data Exchange Format

2519 No Restriction. JSON is popular
2520 Transport
2521 Only HTTP
2522 Service Definition
2523 No Standard. WADL/Swagger/...

68. What are the Best Practices of RESTful Services?

Best Practices in RESTful Design -

- Consumer First - what kind of consumers we have, what is there language, what consumer wants, how will it consume it, is it a web app or mobile app, etc.
- Have good documentation
- Make best use of HTTP
- Request Methods
 - GET
 - POST
 - PUT
 - DELETE
- Response Status - Send the appropriate response status.
 - 200 - SUCCESS
 - 404 - RESOURCE NOT FOUND
 - 400 - BAD REQUEST //validation error in a request
 - 201 - CREATED //successful post request to create a resource
 - 401 - UNAUTHORIZED
 - 500 - SERVER ERROR
- No Secure Info in URI
- Use Plurals
 - Prefer /users to /user
 - Prefer /users/1 to /user/1

69. Can you show the code for an example Get Resource method with Spring REST?

What happens when we return a bean from a Request Mapping Method?

What is GetMapping and what are the related methods available in Spring MVC?

```
@GetMapping("/users")
public List<User> retrieveAllUsers() {
    return service.findAll();
}
```

@GetMapping is shortcut to @RequestMapping. Similar is @PostMapping, @PutMapping, @DeleteMapping.

We are returning a List<user> as a response, so how does this gets converted into a JSON or whatever format our response has. It happens due to MessageConverters. When we use Spring Boot to develop RESTful services, spring boot registers MessageConverters by default. The default MessageConverters for JSON format is Jackson. So when we return a List<User> it will be converted to JSON and JSON response is send back.

70. Can you show the code for an example Post Resource method with Spring REST?

Why do we use ResponseEntity in a RESTful Service?

```
@PostMapping("/users")
public ResponseEntity<Object> createUser(@Valid @RequestBody User user) {

    User savedUser = service.save(user);

    URI location = ServletUriComponentsBuilder
        .fromCurrentRequest()                // /users
        .path("/{id}")                      // /users/{id} - id
        .buildAndExpand(savedUser.getId()).toUri(); //URI for new resource
        is created. /users/10

    return ResponseEntity.created(location).build();
}
```

```

2580         //ResponseEntity.created - indicates status of created.
2581     }
2582
2583     @RequestBody annotation will map POST request content with User object.
2584
2585     Later in code we have send a Created status as response and a URI for the created
2586     user in the response.
2587
2588     We needed @ResponseEntity because we wanted to send status as Created with URI of
2589     created resource, we didn't wanted Success.
2590
2591 71. What is HATEOAS?
2592     Can you give an Example Response for HATEOAS?
2593     How do we implement it using Spring?
2594
2595     HATEOAS: Hypermedia as The Engine of Application State.
2596
2597     Example:
2598
2599         When requested for details of a facebook post, we return
2600         Link for actions to like, unlike or comment on the post
2601
2602         Its not just showing the data, but also the actions which we can do with the
2603         data.
2604         When we return a response don't just return a data, also return what actions
2605         consumer can do with that data or consumer might be intrested in.
2606
2607     {
2608         "id": 1,
2609         "name": "Adam",
2610         "birthDate": "2017-07-19T09:26:18.337+0000",
2611         "_links": {
2612             "all-users": {
2613                 "href": "http://localhost:8080/users"
2614             }
2615         }
2616     }
2617
2618     We can implement this by add a spring starter and then using a Resource class.
2619
2620     <dependency>
2621         <groupId>org.springframework.boot</groupId>
2622         <artifactId>spring-boot-starter-hateoas</artifactId>
2623     </dependency>
2624
2625     @GetMapping("/users/{id}")
2626     public Resource<User> retrieveUser(@PathVariable int id) {
2627
2628         User user = service.findOne(id);
2629
2630         Resource<User> resource = new Resource<User>(user);
2631
2632         ControllerLinkBuilder linkTo =
2633             linkTo(methodOn(this.getClass()).retrieveAllUsers()); //URI mapped to method
2634             handler retrieveAllUsers will be added
2635
2636         resource.add(linkTo.withRel("all-users"));
2637
2638         return resource;
2639     }
2640
2641 72. How do you document RESTful web services?
2642     Can you give a brief idea about Swagger Documentation?

```

2642 How do you automate generation of Swagger Documentation from RESTful Web Services?
 2643 How do you add custom information to Swagger Documentation generated from RESTful
 Web Services?
 2644 What is Swagger-UI?
 2645
 2646
 2647 Documentation for RESTful web services. There is WADL/Swagger/OpenDocs, etc. for
 documenting RESTful web services.
 2648
 2649 OpenAPI Specification (formerly called the Swagger Specification).
 2650 The specification creates the RESTful contract for your API, detailing all of its
 resources and operations in a human and machine readable format for easy
 development, discovery, and integration.

```

2651 <dependency>
2652   <groupId>io.springfox</groupId>
2653   <artifactId>springfox-swagger2</artifactId>
2654   <version>2.4.0</version>
2655 </dependency>
2656
2657 <dependency>
2658   <groupId>io.springfox</groupId>
2659   <artifactId>springfox-swagger-ui</artifactId>
2660   <version>2.4.0</version>
2661 </dependency>
2662
2663
2664
2665 Configure Swagger and enable it -
2666
2667     @Configuration
2668     @EnableSwagger2
2669     public class SwaggerConfig {
2670
2671         @Bean
2672         public Docket api() {
2673             return new Docket(DocumentationType.SWAGGER_2); //version of specification
2674                 to be used
2675         }
2676     }
2677
2678     .....
2679
2680 Swagger will show following things -
2681     - swagger version
2682
2683     - info - high level information about API - what kind of APIs we are offering,
2684       etc.
2685         - description of api
2686         - version
2687         - title
2688         - termOfServices
2689         - contact
2690         - license
2691
2692     - host - where we are hosting the api
2693
2694     - basepath
2695
2696     - tags - are something which we can use to group resources. So for each of our
2697       resource and resource methods we can assign tags.
2698
2699     - paths - shows the details of all the resources that we are exposing and the
2700       different operations that can be performed on each of these resources.
2701       /users: {...}
2702         - get: {
2703             - tags:{...}
2704             - summary:{...}
2705             - operationId:{...}
  
```

```

2703         - consumes:{...}
2704         - produces:{...}
2705         - responses:{
2706             - 200: {...}
2707             ...
2708         }
2709     }
2710     - post:{...}
2711
2712 /error: {...}
2713     - get: {...}
2714     - post:{...}
2715
2716 /helloworld: {...}
2717     - get: {...}
2718     - post:{...}
2719

```

- definitions - includes different elements that are used in our API, eg - what is inside User, etc.

```

2722     - User: {
2723         type: "object",
2724         properties:{
2725             - birthdate: {...}
2726         }
2727     }
2728

```

When we want to expose our swagger document to client then there are two ways -

- We can download it as json
- Or we can use Swagger-UI

.....

Customizing Swagger more:

```

2738 public static final Contact DEFAULT_CONTACT = new Contact("Ranga Karanam",
2739 "http://www.in28minutes.com", "in28minutes@gmail.com");
2740
2741 public static final ApiInfo DEFAULT_API_INFO = new ApiInfo("Awesome API Title",
2742 "Awesome API Description", "1.0", "urn:tos", DEFAULT_CONTACT, "Apache 2.0",
2743 "http://www.apache.org/licenses/LICENSE-2.0");
2744
2745 private static final Set<String> DEFAULT_PRODUCES_AND_CONSUMES = new
2746 HashSet<String>(Arrays.asList("application/json", "application/xml"));
2747

```

now we can use above defined constants in our Docket bean -

```

2746 @Bean
2747 public Docket api() {
2748     return new Docket(DocumentationType.SWAGGER_2)
2749         .apiInfo(DEFAULT_API_INFO)
2750         .produces(DEFAULT_PRODUCES_AND_CONSUMES)
2751         .consumes(DEFAULT_PRODUCES_AND_CONSUMES);
2752 }
2753

```

Above constants in bean will add information in info, if we want to add more details in definitions for User properties then we need to do more in User Entity class -

```

2755 @ApiModel(description="All details about the user.")
2756 @Entity
2757 public class User {
2758
2759     @Size(min=2, message="Name should have atleast 2 characters")
2760     @ApiModelProperty(notes="Name should have atleast 2 characters")
2761     //This will also appear in Swagger doc.
2762     private String name;
2763

```

```
2764     @Past
2765     @ApiModelProperty(notes="Birth date should be in the past")
2766     private Date birthDate;
```

```
2767
2768     .....
2769
```

```
2770 We can use many other annotations to improve the documentation. Its present in
2771 swagger-annotations.jar
```

```
2772 ctrl + 1 => shortcut to create undeclared something.
2773
2774
```

73. What is "Representation" of a Resource?

What is Content Negotiation?

Which HTTP Header is used for Content Negotiation?

How do we implement it using Spring Boot?

How do you add XML support to your RESTful Services built with Spring Boot?

```
2780
2781
2782 A resource can have different representations
```

- 2783 - XML
- 2784 - HTML
- 2785 - JSON

```
2786
2787 JSON is default when we develop in spring boot.
2788
```

```
2789 GET http://localhost:8080/users
```

```
2790 [
2791     {
2792         "id": 2,
2793         "name": "Eve",
2794         "birthDate": "2017-07-19T04:40:20.796+0000"
2795     },
2796     {
2797         "id": 3,
2798         "name": "Jack",
2799         "birthDate": "2017-07-19T04:40:20.796+0000"
2800     }
2801 ]
2802
```

```
2803 Using Accept header we can tell that we want a XML response back. Accept
2804 application/xml or application/json
```

```
2805 GET http://localhost:8080/users
```

```
2806
2807 - Accept application/xml
2808
```

```
2809 <List>
2810     <item>
2811         <id>2</id>
2812         <name>Eve</name>
2813         <birthDate>2017-07-19T10:25:20.450+0000</birthDate>
2814     </item>
2815     <item>
2816         <id>3</id>
2817         <name>Jack</name>
2818         <birthDate>2017-07-19T10:25:20.450+0000</birthDate>
2819     </item>
2820 </List>
2821
2822
```

```
2823 When we are sending a GET request then Accept header - application/xml or
2824 application/json
```

```
2825 When we are sending a POST request then Content-type - application/xml or
2826 application/json
```

```
2827 Representation is format we are using to represent a resource, it can XML or json.
2828
```

```
Content Negotiation is , when we are sending Accept header - application/xml the
```

server response with XML, when we are Accept header - application/json then it responses json. Its the negotiation happening between server and client, the client says I want it in this format and server sends in that format.

Add XML support -

```
<dependency>
  <groupId>com.fasterxml.jackson.dataformat</groupId>
  <artifactId>jackson-dataformat-xml</artifactId>
</dependency>
```

When we add above dependency spring will automatically configure the XML MessageConverters.

74. How do you implement Exception Handling for RESTful Web Services?

What are the different error status that you would return in RESTful Web Services?

How would you implement them using Spring Boot?

How do you handle Validation Errors with RESTful Web Services?

Check code in his git...

Response Status:

```
200 - SUCCESS
201 - CREATED
404 - RESOURCE NOT FOUND
400 - BAD REQUEST
401 - UNAUTHORIZED
500 - SERVER ERROR
```

GET http://localhost:8080/users/1000 - Get request to a non existing resource.

.....in code.....

```
if(user==null)
    throw new UserNotFoundException("id-" + id);           //This is send
    response like below -
```

.....

```
{
  "timestamp": "2017-07-19T05:28:37.534+0000",
  "status": 500,                                           //it is 500, it
  should be 404
  "error": "Not Found",
  "message": "id-500",
  "path": "/users/500"
}
```

To get status of 404 we need to add a annotation on UserNotFoundException class -

```
@ResponseStatus(HttpStatus.NOT_FOUND)
public class UserNotFoundException extends RuntimeException {
.....
```

GET http://localhost:8080/users/1000 - Get request to a non existing resource. - Default Spring Boot Structure -

```
{
  "timestamp": "2017-07-19T05:28:37.534+0000",
  "status": 404,
  "error": "Not Found",
  "message": "id-500",
  "path": "/users/500"
}
```

```

2890         We can customize this default spring boot structure -
2891
2892 GET http://localhost:8080/users/1000 - Get request to a non existing resource. -
The response shows a Customized Message Structure
2893
2894     {
2895         "timestamp": "2017-07-19T05:31:01.961+0000",
2896         "message": "id-500",
2897         "details": "Any details you would want to add"
2898     }
2899
2900     We can do this using defining ExceptionResponse -
2901
2902 public class ExceptionResponse {
2903     private Date timestamp;
2904     private String message;
2905     private String details;
2906
2907
2908     Secondly we will have to implement custome response handling by extending class
ResponseEntityExceptionHandler. ResponseEntityExceptionHandler has default
structure implemented, so we will override it -
2909
2910 @ControllerAdvice                                //because it applies to all the controllers
2911 @RestController
2912 public class CustomizedResponseEntityExceptionHandler extends
ResponseEntityExceptionHandler {
2913
2914     .....
2915
2916     @ExceptionHandler(Exception.class)
2917     public final ResponseEntity<Object> handleAllExceptions(Exception ex, WebRequest
request) {
2918
2919         ExceptionResponse exceptionResponse = new ExceptionResponse(new Date(),
ex.getMessage(), request.getDescription(false));                //our own response
object
2920         return new ResponseEntity(exceptionResponse, HttpStatus.INTERNAL_SERVER_ERROR);
2921     }
2922
2923     .....
2924
2925     @ExceptionHandler(UserNotFoundException.class)
2926     public final ResponseEntity<Object>
handleUserNotFoundException(UserNotFoundException ex, WebRequest request) {
2927
2928         ExceptionResponse exceptionResponse = new ExceptionResponse(new Date(),
ex.getMessage(), request.getDescription(false));
2929
2930         return new ResponseEntity(exceptionResponse, HttpStatus.NOT_FOUND);
2931     }
2932
2933     .....
2934
2935
2936 POST http://localhost:8080/users with Validation Errors
2937
2938 {
2939     "name": "R",                                //More than two chars
2940     "birthDate": "2000-07-19T04:29:24.054+0000"    //should be in past
2941 }
2942
2943 We can add above validation using java validation api -
2944
2945 @Entity
2946 public class User {
2947
2948     @Id
2949     @GeneratedValue

```

```

2950     private Integer id;
2951
2952     @Size(min=2, message="Name should have atleast 2 characters")
2953     @ApiModelProperty(notes="Name should have atleast 2 characters")
2954     private String name;
2955
2956     @Past
2957     @ApiModelProperty(notes="Birth date should be in the past")
2958     private Date birthDate;
2959
2960
2961

```

Once we have added validations on the bean we can then add the invocation of our validation onto our resource. When someone is calling a POST request we would want to do binding and then invoke these validations. We do it using @Valid annotation -

```

2962
2963     @PostMapping("/users")
2964     public ResponseEntity<Object>
2965         createUser(@Valid @RequestBody User user) {
2966

```

So whenever any one send a request, first the validation on User will get fired. If its not valid then it will throw an exception. Add the custom exception response -

```

2968
2969     @Override
2970     protected ResponseEntity<Object>
2971     handleMethodArgumentNotValid(MethodArgumentNotValidException ex, HttpHeaders
2972     headers, HttpStatus status, WebRequest request) {
2973
2974         ExceptionResponse exceptionResponse = new ExceptionResponse(new Date(),
2975         "Validation Failed", ex.getBindingResult().toString());
2976
2977         return new ResponseEntity(exceptionResponse, HttpStatus.BAD_REQUEST);
2978     }

```

.....

Response - 400 Bad Request

```

2980
2981     {
2982         "timestamp": "2017-07-19T09:00:27.912+0000",
2983         "message": "Validation Failed",
2984         "details": "org.springframework.validation.BeanPropertyBindingResult:
2985         1 errors\nField error in object 'user' on field 'name': rejected value [R];
2986         codes [Size.user.name,Size.name,Size.java.lang.String,Size]; arguments
2987         [org.springframework.context.support.DefaultMessageSourceResolvable: codes
2988         [user.name,name]; arguments []; default message [name],2147483647,2];
2989         default message [Name should have atleast 2 characters]"
2990     }

```

75. Why do we need Versioning for RESTful Web Services?
 What are the versioning options that are available?
 How do you implement Versioning for RESTful Web Services?

```

2994
2995     public class PersonV1 {
2996         private String name;
2997
2998         public PersonV1() {
2999             super();
3000         }
3001
3002         public PersonV1(String name) {
3003             super();
3004             this.name = name;
3005         }
3006
3007         public String getName() {
3008             return name;
3009         }

```

```

3010
3011     public void setName(String name) {
3012         this.name = name;
3013     }
3014 }
3015
3016 PersonV1 is the version 1 class and in next version it was updated to -
3017
3018 public class PersonV2 {
3019     private Name name;
3020
3021     public PersonV2() {
3022         super();
3023     }
3024
3025     public PersonV2(Name name) {
3026         super();
3027         this.name = name;
3028     }
3029
3030     public Name getName() {
3031         return name;
3032     }
3033
3034     public void setName(Name name) {
3035         this.name = name;
3036     }
3037 }

```

```

3038
3039 public class Name {
3040     private String firstName;
3041     private String lastName;
3042
3043     public Name() {
3044     }
3045
3046     public Name(String firstName, String lastName) {
3047         super();
3048         this.firstName = firstName;
3049         this.lastName = lastName;
3050     }
3051
3052     public String getFirstName() {
3053         return firstName;
3054     }
3055
3056     public void setFirstName(String firstName) {
3057         this.firstName = firstName;
3058     }
3059
3060     public String getLastName() {
3061         return lastName;
3062     }
3063
3064     public void setLastName(String lastName) {
3065         this.lastName = lastName;
3066     }
3067 }
3068

```

Who ever is using the first version of a service will not be able to use the second version of the service because the structure of response has changed. The old consumers are still expecting name to be returned as String. We can solve this by giving two different versions to same api.

Versioning Options:

- URI Versioning

```

3077         http://localhost:8080/v1/person
3078         http://localhost:8080/v2/person
3079
3080     - Request Param Versioning
3081         http://localhost:8080/person/param?version=1
3082         http://localhost:8080/person/param?version=2
3083
3084     - Header Versioning
3085         http://localhost:8080/person/header
3086         headers=[X-API-VERSION=1]
3087
3088         i.e in postman select Headers - put Key as X-API-VERSION and value as 1
3089
3090         http://localhost:8080/person/header
3091         headers=[X-API-VERSION=2]
3092
3093     - MIME Type or Accept Header Versioning
3094         http://localhost:8080/person/produces
3095         produces=[application/vnd.company.app-v1+json]           //We will
3096         expect client to send accept headers like this.
3097
3098         i.e in postman select Headers - select Key as Accept and pass value
3099         as application/vnd.company.app-v1+json
3100
3101         http://localhost:8080/person/produces
3102         produces=[application/vnd.company.app-v2+json]
3103
3104         called MIME type because application/json is MIME
3105
3106 @RestController
3107 public class PersonVersioningController {
3108
3109     @GetMapping("v1/person")
3110     public PersonV1 personV1() {
3111         return new PersonV1("Bob Charlie");
3112     }
3113
3114     @GetMapping("v2/person")
3115     public PersonV2 personV2() {
3116         return new PersonV2(new Name("Bob", "Charlie"));
3117     }
3118
3119     @GetMapping(value = "/person/param", params = "version=1")
3120     public PersonV1 paramV1() {
3121         return new PersonV1("Bob Charlie");
3122     }
3123
3124     @GetMapping(value = "/person/param", params = "version=2")
3125     public PersonV2 paramV2() {
3126         return new PersonV2(new Name("Bob", "Charlie"));
3127     }
3128
3129     @GetMapping(value = "/person/header", headers = "X-API-VERSION=1")
3130     public PersonV1 headerV1() {
3131         return new PersonV1("Bob Charlie");
3132     }
3133
3134     @GetMapping(value = "/person/header", headers = "X-API-VERSION=2")
3135     public PersonV2 headerV2() {
3136         return new PersonV2(new Name("Bob", "Charlie"));
3137     }
3138
3139     @GetMapping(value = "/person/produces", produces =
3140         "application/vnd.company.app-v1+json") //produces attribute indicates what
3141         kind of output this service is producing. Here we are appending something to it
3142         to differentiate for versions
3143     public PersonV1 producesV1() {
3144         return new PersonV1("Bob Charlie");
3145     }

```

```

3141
3142     @GetMapping(value = "/person/produces", produces =
3143         "application/vnd.company.app-v2+json")
3144     public PersonV2 producesV2() {
3145         return new PersonV2(new Name("Bob", "Charlie"));
3146     }
3147 }
3148

```

Versioning

```

3150     Media type versioning (a.k.a "content negotiation" or "accept header") -
3151     we cannot execute this type directly on browser, we will need client like postman
3152     GitHub
3153     (Custom) headers versioning - we cannot execute this type directly
3154     on browser, we will need client like postman
3155     Microsoft
3156     URI Versioning
3157     Twitter
3158     Request Parameter versioning
3159     Amazon

```

Versioning

- Factors
 - URI Pollution
 - Misuse of HTTP Headers - because http headers were not ment for versioning of apis.
 - Caching
 - Can we execute the request on the browser?
 - API Documentation
- No Perfect Solution

76. Which is the client you use to test RESTful Web Services?
 How do you use Postman to execute RESTful Service Requests?
 How can you send Request Headers using Postman?

check Diagram.
